### Introduction 1

This book will eventually become the reference manual of  $LUAT_EX$ . At the moment, it simply reports the behaviour of the executable matching the snapshot or beta release date in the title

Features may come and go. The current version of LUATFX is not meant for production and users cannot depend on stability, nor on functionality staying the same.

Nothing is considered stable just yet. This manual therefore simply reflects the current state of the executable. Absolutely nothing on the following pages is set in stone. When the need arises, anything can (and will) be changed without prior notice.

If you are not willing to deal with this situation, you should wait for the stable version. Currently we expect the first release to be available sometime in the summer of 2008.

LUATEX consists of a number of interrelated but (still) distinguishable parts:

- $PDFT_FX$  version 1.40.3
- ALEPH RC4 (from the TEXLIVE repository)
- Lua 5.1.2
- Dedicated *Lua* libraries
- Various  $T_FX$  extensions
- Parts of FontForge 2007.06.07
- Newly written compiled source code to glue it all together

Neither ALEPH's I/O translation processes, nor tcx files, nor ENCTEX can be used, these encodingrelated functions are superseded by a LuA-based solution (reader callbacks). Also, some experimental  $PDFT_EX$  features are removed. These can be implemented in Lua instead.

# Basic T<sub>E</sub>X enhancements

### Version information 2.1

There are three new primitives to test the version of *LuATEX*:

primitive explanation

\luatexversion A combination of major an minor number, as in pdfTeX. Current value: 11

The revision, as in pdfTeX. Current value: 0 \luatexrevision

\luatexdatestamp A combination of the local date and hour when the current executable was

compiled, the syntax is identical to \luatexrevision. Value for the exe-

cutable that generated this document: 2007082011.

Note that the \luatexdatestamp depends on both the compilation time and compilation place of the current executable, it is defined in terms of the local time. The purpose of this primitive is solely to be an aid in the development process, do not use it for anything besides debugging.

# 2.2 UNICODE text support

Text input and output is now considered to be UNICODE text, so input characters can use the full range of *Unicode*  $(2^{20} + 2^{16} = 10FFFF = 1114111)$ .

Later chapters will talk of characters and glyphs. Although these are not the interchangeable, they are closely related. During typesetting, a character is always converted to a suitable graphic representation of that character in a specific font. However, while processing a list of to-be-typeset nodes, its contents may still be seen as a character. Inside  $LUAT_FX$  there is not yet a clear separation between the two concepts yet. Until this is implemented, please do not be too harsh on us if we make errors in the usage of the terms.

Note: for now, it only makes sense to use values above the base plane ("0xFFFF) for \mathcode and \catcode assignments, since the hyphenation patterns are still limited to at the most 16-bit values, so the other commands will not know what to do with those high values.

A few primitives affected by this, all in a similar fashion: each of them has to accomodate for a larger range of acceptable numbers. For instance, \char now accepts values between 0 and 1114111. This should not be a problem for well-behaved input files, but it could create incompatibilities for input that would have generated an error when processed by older TFX-based engines. The maximum number of allocations is "10FFFF or  $2^{20} + 2^{16}$  (21 bits). The maximum value that can be assigned are:

primitive	bits	hex	numeric
\char	21	10FFFF	$2^{20} + 2^{16}$
\chardef	21	10FFFF	$2^{20} + 2^{16}$

```
\lccode 21 10FFFF 2^{20} + 2^{16}
\uccode 21 10FFFF 2^{20} + 2^{16}
\sfcode 15 7FFF 2^{15}
\catcode 4 F 2^4
```

As far as the core engine is concerned, all input and output to text files is *UTF*-8 encoded. Input files can be pre-processed using the **reader** callback. This will be explained in a later chapter.

Output in byte-sized chunks can be achieved by using characters just outside of the valid unicode range, starting at the value 1.114.112 (0x110000). When the times comes to print a character c >= 1.114.112,  $LuAT_FX$  will actually print the single byte corresponding to c - 1.114.112.

Output to the terminal uses  $^{\sim}$  notation for the lower control range (c < 32), with the exception of  $^{\sim}$ I,  $^{\sim}$ J and  $^{\sim}$ M. These are considered 'safe' and therefore printed as-is.

Normalization of the *Unicode* input can be handled by a macro package during callback processing (this will be explained in section 4.6.2).

# 2.3 Wide math characters

Text handling is now extended up to the full *UNICODE* range, but math mode deals mostly with glyphs in fonts directly and fonts tend to be 16-bit at maximum. The extension from 8-bit to 16-bit was already present in *ALEPH* by means of a set of extra primitives.

Therefore, the math primitives from  $T_EX$  and  $A_{LEPH}$  are kept mostly as they are, except for the ones that convert from input to math commands like matcode and omathcode. The traditional  $T_EX$  primitives are unchanged, their arguments are upscaled from 8 to 16 bits internally (as in  $A_{LEPH}$ ).

primitive	max index/bits	hex	numeric
\mathchardef	15	8000	$2^3 \times 2^8 \times 2^4$
\mathcode	15	8000	$2^3 \times 2^8 \times 2^4$
\delcode	27	7FFFFF	$2^3 \times 2^4 \times 2^8 \times 2^4 \times 2^8$
\mathchar	15	7FFF	$2^3 * 2^8 * 2^4$
\delimiter	27	7FFFFF	$2^3 * 2^4 * 2^8 * 2^4 * 2^8$
\omathchar	27	7FFFFF	$2^3 * 2^{16} * 2^8$
\odelimiter	27+24	7FFFFFF + FFFFFF	$2^3 * 2^8 * 2^{16} + 2^8 * 2^{16}$
\omathchardef	21=27	10FFFF = 8000000	$2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$
\omathcode	21=27	10FFFF = 8000000	$2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$
\odelcode	21 = 27 + 24	10FFFF = 7FFFFFF	$2^{20} + 2^{16} = 2^3 * 2^8 * 2^{16}$
		+ FFFFFF	$+2^8*2^{16}$

# 2.4 Extended tables

All traditional  $T_EX$  and  $\varepsilon$ - $T_EX$  registers can be 16 bit numbers as in  $A_{LEPH}$ . The affected commands are:

\count	\countdef	\unhbox	\ht
\dimen	\dimendef	\unvbox	\dp
\skip	\skipdef	\сору	\setbox
\muskip	\muskipdef	\unhcopy	\vsplit
\marks	\toksdef	\unvcopy	
\toks	\box	\wd	

The same is true for the font-related *PDFTEX* tables like \rpcode etc.

### 2.5 Attribute registers

Attributes are a completely new concept in LVATFX. Syntactically, they behave a lot like counters: attributes obey TFX's nesting stack and can be used after \the etc. just like the normal \count registers.

```
\attribute \langle 16-bit number \rangle \langle optional equals \rangle \langle 31-bit number \rangle
\attributedef \langle csname \rangle \langle optional equals \rangle \langle 16-bit number \rangle
```

Conceptually, an attribute is either 'set' or 'unset'. Set attributes can only have values of 0 or more, otherwise they are considered unset and automatically remapped to an special negative value meaning 'unset' (currently that value is -1, but please test on negativity, not on a specific value). All attributes start out in the 'unset' state (in INITEX).

Attributes can be used as extra counter values, but their usefulness comes mostly from the fact that the numbers and values of all 'set' attributes are attached to all nodes created in their scope. These can then be queried from any LvA code that deals with node processing. Future versions of  $LvAT_FX$ will propably be using specific negative attribute ids for internal use. Further information about how to use attributes for node list processing from lua is given in chapter 6.

# LUA related primitives

In order to merge LuA code with TEX input, a few new primitives are needed. LuATEX has support for 65536 separate LUA interpreter states. States are automatically created based on the integer argument to the primitives \directlua and \latelua.

### 2.6.1 \directlua

The primitive \directlua is used to execute LUA code immediately. The syntax is

```
\directlua \langle 16-bit number \rangle \langle general text \rangle
```

The  $\langle \text{general text} \rangle$  is fed into the LuA interpreter state indicated by the  $\langle 16\text{-bit number} \rangle$ . If the state does not exist yet, it will be initialized automatically. The current category codes are applied to the (general text), and it is passed on as if it was displayed using \the\toks. On the LUA side, each of these blocks is treated as a chunk comprising a single line. This means that you can

not use LVA line comments (starting with --) within the argument, as that will last for the rest of the input. You need to use  $T_EX$ -style comments (starting with %) instead.

This command is expandable. As an example, the following input:

```
$\pi = \directluaO{tex.print(math.pi)}$
```

will result in  $\pi = 3.1415926535898$ 

Because the  $\langle \text{general text} \rangle$  is a chunk, the normal  $L \cup A$  error handling is triggered if there is a problem in the included code. The  $L \cup A$  error messages should be clear enough, but the contextual information is still pretty bad. Typically, you will only see the line number of the right brace at the end of the code.

While on the subject of errors: some of the things you can do inside LvA code can break up  $LvAT_EX$  pretty bad. If you are not careful while working with the node list interface, you may even end up with assertion errors from within the  $T_EX$  portion of the executable.

# 2.6.2 \latelua

\latelua stores LUA code in a whatsit that will be processed inside the output routine. It's intended use is very similar to \pdfliteral. Within the LUA code, you can print PDF statements directly to the PDF file.

\latelua \lambda 16-bit number \rangle \general text \rangle

# 2.6.3 \luaescapestring

This primitive converts a  $T_EX$  token sequence so that it can be safely used as the contents of a LUA string: embedded backslashes, double quotes and single quotes are escaped by prepending an extra token consisting of a backslash with category code 12.

```
\luaescapestring \( \text{general text} \)
```

Most often, this command is not actually the best way to deal with the differences between the  $T_EX$  and LUA. In very short bits of LUA code it is often not needed, and for longer stretches of LUA code it is easier to keep the code in a separate file and load it using LUA's dofile:

```
\directlua0 { dofile('mysetups.lua')}
```

# 2.6.4 \closelua

This primitive allows you to close a LUA state, freeing all of its used memory.

```
\closelua \langle 16-bit number \rangle
```

You cannot close the initial LUA state (0), attempts to do so will be silently ignored.

States are never closed automatically except when a fatal out of memory error occurs, at which point LUATEX will exit anyway.

Also be aware that *LuA* states are not closed immediately, but only when the **\output** routine comes into play next (because there may be pending **\latelua** calls).

# 2.7 New $\varepsilon$ -TFX primitives

### 2.7.1 \clearmarks

This primitive clears a marks class completely, resetting all three connected mark texts to empty.  $\clearmarks\ \langle 16\text{-bit number} \rangle$ 

# 2.7.2 \noligs and \nokerns

These primitives prohibit ligature and kerning insertion at the time when the initial node list is built by LUATEXs main control loop. They are part of a temporary trick and will be removed in the near future. For now, you need to enable these primitives when you want to do node list processing of 'characters', where TEXs normal processing would get in the way.

```
\noligs \( \text{integer} \)
\nokerns \( \text{integer} \)
```

# 2.7.3 \formatname

\formatname's syntax is identical to \jobname.

In  $INIT_EX$ , the expansion is empty. Otherwise, the expansion is the value that  $\jobname$  had during the  $INIT_EX$  run that dumped the currently loaded format.

# 2.7.4 \scantextokens

The syntax of \scantextokens is identical to \scantokens.

This is a slightly adapted version of  $\varepsilon$ - $T_EX$ 's \scantokens. The differences are:

- The last (and usually only) line does not have a \endlinechar appended
- \scantextokens never raises an EOF error, and it does not execute \everyeof tokens.
- The '.. while end of file ..' error tests are not executed, allowing the expansion to end on a different grouping level or while a conditional is still incomplete.

### 2.7.5 Catcode tables

Catcode tables are a new feature that allows you to switch to a predefined catcode regime in a single statement. You can have a practically unlimited number of different tables.

The subsystem is backward compatible: if you never use the following commands, your document will not notice any difference in behavior compared to traditional  $T_EX$ .

The contents of each catcode table is independent of any other catcode tables, and their contents is stored and retrieved from the format file.

### 2.7.5.1 \catcodetable

### \catcodetable \( 28\)-bit number \( \)

The \catcodetable switches to a different catcode table. Such a table has to be previously created using one of the two primitives below, or it has to be zero (table zero is initialized by  $INIT_EX$ ).

### 2.7.5.2 \initcatcodetable

### \initcatcodetable \langle 28-bit number \rangle

The \initcatcodetable creates a new table with catcodes identical to those defined by INITEX:

```
0
                         escape
   ^^M
5
                  return car_ret
   ^^@
9
                          ignore
                  null
10 <space>
                  space
                         spacer
11
   a - z
                         letter
11 A - Z
                         letter
12 everything else
                         other
   %
                         comment
15 ^^?
                  delete invalid char
```

The new catcode table is allocated globally: it will not go away after the current group has ended. If the supplied number is identical to the currently active table, an error is raised.

### 2.7.5.3 \savecatcodetable

### \savecatcodetable \( 28\)-bit number \( \)

\savecatcodetable copies the current set of catcodes to a new table with the requested number. The definitions in this new table are all treated as if they were made in the outermost level.

The new table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

# 2.7.6 Font syntax

LuaTEX will accept a braced argument as a font name:

```
\font\myfont = {cmr10}
```

This allows for embedded spaces, without the need for double quotes. Macro expansion takes place inside the argument.

# 3 LUA general

# 3.1 Initialization

# 3.1.1 LUATFX as a LUA interpreter

There are some situations that make LuATFX behaves like it is a LuA interpreter only:

- If a --luaonly option is given on the commandline
- If the executable is named texlua (or luatexlua)
- if the only non-option argument (file) on the commandline has the extension lua or luc.

In this mode, it will set *LuA*'s arg[0] to the found script name, pushing preceding options in negative values and the rest of the commandline in the positive values, just like the *LuA* interpreter.

LUATEX will exit immediately after executing the specified LUA script and is, in effect, a somewhat bulky standalone LUA interpreter with a bunch of extra preloaded libraries.

# 3.1.2 LUATEX as a LUA byte compiler

There are two situations that make LUATEX behaves like the LUA byte compiler:

- If a --luaconly option is given on the commandline
- If the executable is named texluac

In this mode, LuaTEX is exactly like luac from the standalone Lua distribution, except that it does not have the -l switch, and that it accepts (but ignores) the --luaconly switch.

# 3.1.3 Other commandline processing

When the  $LvaT_EX$  executable starts, it looks for the --lua commandline option. If there is no --lua option, the commandline is interpreted in a similar fashion as in traditional  $PDFT_EX$  and ALEPH. But if the option is present,  $LvaT_EX$  will enter an alternative mode of commandline parsing in comparison to the standard web2c programs.

In this mode, a small series of actions is taken in order. At first, it will only interpret a small subset of the commandline directly:

```
    -lua=s load and execute a LuA initialization script
    -safer disable easily exploitable LuA commands
    -help display help and exit
    -version display version and exit
```

Now it searches for the requested *LuA* initialization script. If it can not be found using the actual name given on the commandline, a second attempt is made by prepending the value of the environment variable LUATEXDIR, if that variable is defined.

Then it checks the **--safer** switch. You can use that to disable some *LuA* commands that can easily be abused by a malicious document. At the moment, this switch nils the following functions:

### library functions

os execute exec setenv rename remove

io popen output tmpfile

lfs rmdir mkdir chdir lock touch

And it makes io.open() fail on files that are opened for anything besides reading.

Next the initialization script is loaded and executed. From within the script, the entire commandline in available in the Lua table arg, beginning with arg[0], containing the name of the executable.

Commandline processing happens very early on. So early, in fact, that none of  $T_EX$ 's initializations have taken place yet. For that reason, the tex, token, node and pdf tables are off-limits during the execution of the startup file (they are nilled). Special care is taken that texio.write and texio.write\_nl function properly, so that you can at least report your actions to the log file when (and if) it eventually becomes opened (note that  $T_EX$  does not even know it's \jobname yet at this point). See chapter 4 for more information about the  $LvAT_EX$ -specific LvA extension tables.

The Lua initialization script is loaded into Lua state 0, and everything you do will remain visible during the rest of the run, with the exception of the aforementioned tex, token, node and pdf tables: those will be initialized to their documented state after the execution of the script. You should not store anything in variables or within tables with these four global names, as they will be overwritten completely.

We recommend you use the startup file only for your own  $T_EX$ -independant initializations (if you need any), to parse the commandline, set values in the texconfig table, and register the callbacks you need.  $LUAT_EX$  will fetch some of the other commandline options from the texconfig table at the end of script execution (see the description of the texconfig table later on in this document for more details on which ones exactly).

Unless the texconfig table tells it not to start KPATHSEA at all (set texconfig.kpse\_init to false for that), LUATEX acts on three more commandline options after the initialization script is finished:

### flag meaning

--fmt=s set the format name

--progname=s set the progname (only for KPATHSEA)

--ini enable INIT<sub>E</sub>X mode

In order to initialize the built-in *KPATHSEA* library properly, *LUATEX* needs to know the correct 'progname' to use, and for that it needs to check -progname (and -ini and -fmt, if -progname is missing).

# 3.2 LUA changes

The read("\*line") function from the io library has been adjusted so that it is line-ending neutral: any of LF, CR or CR+LF are acceptable line endings.

The tostring() printer for numbers has been changed so that it return 0 instead of something like 2e-5 (which confused  $T_EX$  enormously) when the value is so small that  $T_EX$  cannot distinguish it from zero.

Dynamic loading of .so and .dll files is disabled on all platforms.

luafilesystem has been extended with two extra boolean functions (isdir(filename) and isfile(filename)) and one extra string field in it's attributes table (permissions).

The string library has an extra function: string.explode(s[,m]). This function returns an array containing the string argument s split into substrings based on the value of the string argument m. The second argument is a string that is either empty (this splits the string into characters), a single character (this splits on each occurrence of that character, possibly introducing empty strings), or a single character followed by the plus sign + (this special version does not create empty substrings). The default value for m is ` +' (multiple spaces).

The string library also has six extra iterators that return strings piecemeal:

- string.utfvalues(s) (returns an integer value in the *Unicode* range)
- string.utfcharacters(s) (returns a string with a single UTF-8 token in it)
- string.characters(s) (a string containing one byte)
- string.characterpairs(s) (two strings each containing one byte) will produce an empty second string in the string length was odd.
- string.bytes(s) (a single byte value)
- string.bytepairs(s) (two byte values) Will produce nil instead of a number as its second return value if the string length was odd.

The string.characterpairs() and string.bytepairs() are useful especially in the conversion of UTF-16 encoded data into UTF-8.

The os library has a few extra functions and variables:

- os.exec('command') is a non-returning version of os.execute. The advantage of this command is that it cleans out the current process before starting the new one, making it especially useful for use in *TeXLua*.
- os.setenv('key','value') This sets a variable in the environment. Passing nil instead of a value string will remove the variable.
- os.env This is a hash table containing a dump of the variables and values in the process environment at the start of the run. It is writeable, but the actual environment is *not* updated automatically.

In stock Lua, many things depend on the current locale. In  $LvaT_EX$ , we can't do that, because it makes documents unportable. While  $LvaT_EX$  is running if forces the following locale settings:

LC\_CTYPE=C LC\_COLLATE=C LC NUMERIC=C

# 3.3 LUA Modules

Some modules that are normally external to Lua are statically linked in with LUATEX, because they offer useful functionality:

- slnunicode, from the Selene libraries, http://luaforge.net/projects/sln. (version 1.1)
- luazip, from the kepler project, http://www.keplerproject.org/luazip/. (version 1.2.1, but patched for compilation with lua 5.1)
- luafilesystem, also from the kepler project, http://www.keplerproject.org/luafilesystem/. (version 1.2, but patched for compilation with lua 5.1)
- lpeg, by Roberto Ierusalimschy, http://www.inf.puc-rio.br/~roberto/lpeg.html. (version 0.6)
- Izlib, by Tiago Dionizio, http://mega.ist.utl.pt/~tngd/lua/. (version 0.2)
- $\bullet \quad md5, \ by \ Roberto \ lerusalimschy \ http://www.inf.puc-rio.br/\sim roberto/md5/md5-5/md5.html.$

# 4 LUATEX LUA Libraries

The interfacing between  $T_EX$  and LUA is facilitated by a set of library modules. The LUA libraries in this chapter are all defined and initialized by the  $LUAT_EX$  executable. Together, they allow LUA scripts to query and change a number of  $T_EX$ 's internal variables, run various internal functions  $T_EX$ , and set up  $LUAT_EX$ 's hooks to execute LUA code.

# 4.1 The tex library

The tex table contains a large list of virtual internal  $T_EX$  parameters that are partially writable.

The designation 'virtual' means that these items are not properly defined in LUA, but are only frontends that are handled by a metatable that operates on the actual  $T_EX$  values. As a result, most of the LUA table operators (like pairs and #) do not work on such items.

At the moment, it is possible to access almost every parameter that has these characteristics:

- You can use it after \the
- It is a single token.

This excludes parameters that need extra arguments, like \the\scriptfont.

The subset comprising simple integer and dimension registers are writable as well as readable (stuff like \tracingcommands and \parindent).

# 4.1.1 Integer parameters

The integer parameters accept and return *LuA* numbers.

### 4.1.7 Convert commands

The supported commands at this moment are:

tex.AlephVersiontex.eTeXrevisiontex.pdfnormaldeviatetex.Alephrevisiontex.formatnametex.pdftexbannertex.OmegaVersiontex.jobnametex.pdftexrevisiontex.Omegarevisiontex.luatexrevision

tex.eTeXVersion tex.luatexdatestamp

All 'convert' commands are read-only and return a LuA string

If you are wondering why this list looks haphazard; these are all the cases of the 'convert' internal command that do not require an argument.

# 4.1.8 attribute, count, dimension and token registers

 $T_EX$ s attributes (\attribute), counters (\count), dimensions (\dimen) and token (\toks) registers can be accessed and written to using four virtual sub-tables of the tex table:

tex.attribute tex.dimen tex.count tex.toks

It is possible to use the names of relevant \attributedef, \countdef, \dimendef, or \toksdef control sequences as indices to these tables:

```
tex.count.scratchcounter = 0
enormous = tex.dimen['maxdimen']
```

In this case,  $LuaT_EX$  looks up the value for you on the fly. You have to use a valid \countdef (or \attributedef, or \dimendef, or \toksdef), anything else will generate an error (the intent is to eventually also allow <chardef tokens> and even macros that expand into a number)

The attribute and count registers accept and return *LuA* numbers.

The dimension registers accept LUA numbers (in scaled points) or strings (with an included absolute dimension; em and ex and px are forbidden). The result is always a number in scaled points.

The token registers accept and return *LuA* strings. *LuA* strings are converted to token lists using \the\toks style expansion.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setdimen(number n, string s)
tex.setdimen(string s, string s)
tex.setdimen(number n, number n)
tex.setdimen(string s, number n)
number n = tex.getdimen(number n)
number n = tex.getdimen(string s)

tex.setcount(number n, number n)
tex.setcount(string s, number n)
number n = tex.getcount(number n)
number n = tex.getcount(string s)

tex.settoks (number n, string s)
tex.settoks (string s, string s)
string s = tex.gettoks (number n)
string s = tex.gettoks (string s)
```

# 4.1.9 Box registers

The current dimensions of \box registers can be read and altered using three other virtual subtables :

```
tex.wd
tex.ht
tex.dp
```

These are indexed strictly by number.

The box size registers accept LUA numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setboxwd(number n, number n)
number n = tex.getboxwd(number n)
tex.setboxht(number n, number n)
number n = tex.getboxht(number n)
```

```
tex.setboxdp(number n, number n)
number n = tex.getboxdp(number n)
```

It is also possible to set and query actual boxes, using the node interface as defined in the node library:

```
tex.box
for array access, or
tex.setbox(number n, <node> s)
<node> n = tex.getbox(number n)
```

for function-based access

Be warned that an assignment like

```
tex.box[0] = tex.box[2]
```

does not copy the node list, it just duplicates a node pointer. If box2 will be cleared by  $T_EX$  commands later on, the contents of box0 becomes invalid as well. To prevent this from happening, always use node.copy\_list() unless you are assigning to a temporary variable:

```
tex.box[0] = node.copy_list(tex.box[2])
```

### 4.1.10 Print functions

The tex table also contains the three print functions that are the major interface from LvA scripting to  $T_FX$ .

The arguments to these three functions are all stored in an in-memory virtual file that is fed to the  $T_EX$  scanner as the result of the expansion of \directlua.

The total amount of returnable text from a  $\operatorname{directlua}$  command is only limited by available system *RAM*. However, each separate printed string has to fit completely in  $T_EX$ s input buffer.

# 4.1.10.1 tex.print

```
tex.print(string s, ...)
tex.print(number n, string s, ...)
```

Each string argument is treated by  $T_EX$  as a separate input line.

The optional parameter can be used to print the strings using the catcode regime defined by  $\catcodetable\ n$ . If n is not a valid catcode table, then it is ignored, and the currently active catcode regime is used instead.

The very last string of the very last tex.print() command in a \directlua will not have the \endlinechar appended, all others do.

# **4.1.10.2** tex.sprint

```
tex.sprint(string s, ...)
tex.sprint(number n, string s, ...)
```

Each string argument is treated by  $T_EX$  as a special kind of input line that makes it suitable for use as a partial line input mechanism:

- $\bullet$   $T_EX$  does not switch to the 'new line' state, so that leading spaces are not ignored.
- No \endlinechar is inserted.
- Trailing spaces are not removed.

### 4.1.10.3 tex.write

```
tex.write(string s, ...)
```

Each string argument is treated by  $T_EX$  as a special kind of input line that makes is suitable for use as a quick way to dump information:

- All catcodes on that line are either 'space' (for ' ') or 'character' (for all others).
- There is no \endlinechar appended.

# 4.1.11 Helper functions

### 4.1.11.1 tex.round

```
number n = tex.round(number o)
```

Rounds lua number o, and returns a number that is in the range of a valid  $T_EX$  register value. If the number starts out of range, it generates a 'Number to big' error as well.

### 4.1.11.2 tex.scale

```
number n = tex.scale(number o, number delta)
table n = tex.scale(table o, number delta)
```

Multiplies the lua numbers o and delta, and returns a rounded number that is in the range of a valid  $T_FX$  register value. In the table version, it creates a copy of the table with all numeric top—

level values scaled in that manner. If the mutiplied number(s) are of range, it generates 'Number to big' error(s) as well.

# 4.2 The token library

The token table contains interface functions to  $T_EX$ 's handling of tokens. These functions are most useful when combined with the token\_filter callback, but they could be used standalone as well.

A token is represented in *LuA* as a small table. For the moment, this table consists of three numeric entries:

nr	meaning	description
1	command code	this is a value between 0 and 130 (approximately)
2	command modifier	this is a value between 0 and $2^{21}$
3	control sequence id	for commands that are not te result of control sequences, like letters and
		characters, it is zero, otherwise, it is number pointing into the 'equivalence
		table'

# 4.2.1 token.get\_next

```
token t = token.get_next()
```

This fetches the next input token from the current input source, without expansion.

# 4.2.2 token.is\_expandable

```
boolean b = token.is_expandable(token t)
```

This tests if the token t could be expanded.

# 4.2.3 token.expand

```
token.expand()
```

If a token is expandable, this will expand one level of it, so that the first token of the expansion will now be the next token to be read by tex.get\_next().

# 4.2.4 token.is\_activechar

```
boolean b = token.is activechar(token t)
```

This is a special test that is sometimes handy. Discovering whether some token is the result of an active character turned out to be very hard otherwise.

### 4.2.5 token.create

```
token t = token.create(string csname)
token t = token.create(number charcode)
token t = token.create(number charcode, number catcode)
```

This is the token factory. If you feed it a string, then it is the name of a control sequence (without leading backslash), and it will be looked up in the equivalence table.

If you feed it number, then this is assumed to be an input character, and an optional second number gives its category code. This means it is possible to overrule a character's category code, with a few exceptions: the category codes 0 (escape), 9 (ignored), 13 (active), 14 (comment), and 15 (invalid) cannot occur inside a token. The values 0, 9, 14 and 15 are therefore illegal as input to token.create(), and active characters will be resolved immediately.

Note: unknown string sequences and never defined active characters will result in a token representing an 'undefined control sequence' with a near-random name. It is *not* possible to define brand new control sequences using token.create!

# 4.2.6 token.command\_name

```
string commandname = token.command_name(token t)
```

This returns the name associated with the 'command' value of the token in LvATEX. There is not always a direct connection between these names and primitives. For instance, all  $\in test$  are grouped under if\_fest, and the 'command modifier' defines which test is to be run.

# 4.2.7 token.command id

```
number i = token.command_idtring commandname)
```

This returns a number that is the inverse operation of the previous command, to be used as the first item in a token table.

# 4.2.8 token.csname\_name

```
string csname = token.csname_name(token t)
```

This returns the name associated with the 'equivalence table' value of the token in *LuATEX*. It returns the string value of the command used to create the current token, or an empty string if there is no associated control sequence.

# 4.2.9 token.csname\_id

number i = token.csname\_id(string csname)

This returns a number that is the inverse operation of the previous command, to be used as the third item in a token table.

# 4.3 The node library

The node library contains functions that facilitate dealing with (lists of) nodes and their values. They allow you to alter, create, copy, delete, and insert LVATEX node objects, the core objects within the typesetter.

 $LUAT_EX$  nodes are represented in LUA as userdata with the metadata type luatex.node. The various parts within a node can be accessed using named fields.

Each node has at least the three fields next, id, and subtype:

- The next field returns the userdata object for the next node in a linked list of nodes, or nil, if there is no next node.
- The id indicates TEX's 'node type'. The field id has a numeric value for efficiency reasons, but some of the library functions also accept a string value instead of id.
- The subtype is another number. It often gives further information about a node of a particular
  id, but it is most important when dealing with 'whatsits', because they are differentiated solely
  based on their subtype.

The other available fields depend on the id (and for 'whatsits', the subtype) of the node. Further details on the various fields and their meanings are given in chapter 6.

 $T_EX$ s math nodes are not yet supported: there is not yet an interface to the internals of the math list and it is not possible to create them from LvA. Support for unset (alignment) nodes is partial: they can be queried and modified from LvA code, but not created.

Nodes can be compared to each other, but: you are actually comparing indices into the node memory. This means that equality tests can only be trusted under very limited conditions. It will not work correctly in any situation where one of the two nodes has been freed and/or reallocated: in that case, there will be false positives.

At the moment, memory management of nodes should still be done explicitly by the user. Nodes are not 'seen' by the Lua garbage collector, so you have to call the node free-ing functions yourself when you are no longer in need of a node (list). Nodes form linked lists without reference counting, so you have to be careful that when control returns back to LuaTFX itself, you have not deleted nodes

that are still referenced from a next pointer elsewhere, and that you did not create nodes that are referenced more than once.

# 4.3.1 Node handling functions

# **4.3.1.1** node.types

```
table t = node.types()
```

This function returns an array that maps node id numbers to node type strings, providing an overview of the possible top-level id types.

### 4.3.1.2 node.whatsits

```
table t = node.whatsits()
```

 $T_EX$ s 'whatsits' all have the same id. The various subtypes are defined by their subtype. The function is much like node.id, except that it provides an array of subtype mappings.

### 4.3.1.3 node.id

```
number id = node.id(string type)
```

This converts a single type name to it's internal numeric representation.

# 4.3.1.4 node.subtype

```
number subtype = node.subtype(string type)
```

This converts a single whatsit name to it's internal numeric representation (subtype).

### 4.3.1.5 node.type

```
string type = node.type(number id)
```

This converts a internal numeric representation to an external string representation.

# 4.3.1.6 node.fields

```
table t = node.fields(number id)
table t = node.fields(number id, number subtype)
```

This function returns an array of valid field names for a particular type of node. If you want to get the valid fields for a 'whatsit', you have to supply the second argument also. In other cases, any given second argument will be silently ignored.

This function accepts string id and subtype values as well.

### 4.3.1.7 node.has\_field

```
boolean t = node.has_field(<node> n, string field)
```

This function returns a boolean that is only true if n is actually a node, and it has the field.

### 4.3.1.8 node.new

```
<node> n = node.new(number id)
<node> n = node.new(number id, number subtype)
```

Creates a new node. All of the new node's fields are initialized to either zero or nil except for id and subtype (if supplied). If you want to create a new whatsit, then the second argument is required, otherwise it need not be present. As with all node functions, this function creates an node on the  $T_EX$  level.

This function accepts string id and subtype values as well.

### 4.3.1.9 node.free

```
node.free(<node> n)
```

Removes the node n from TEX's memory. Be careful: no checks are done on whether this node is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

# 4.3.1.10 node.flush\_list

```
node.flush_list(<node> n)
```

Removes the node list n and the complete node list following n from  $T_EX$ 's memory. Be careful: no checks are done on whether any of these nodes is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

### **4.3.1.11** node.copy

```
<node> m = node.copy(<node> n)
```

Creates a deep copy of node n, including all nested lists as in the case of a hlist or vlist node. Only the **next** field is not copied.

# 4.3.1.12 node.copy\_list

```
<node> m = node.copy_list(<node> n)
```

Creates a deep copy of the node list that starts at n.

### 4.3.1.13 node.hpack

```
<node> h = node.hpack(<node> n)
<node> h = node.hpack(<node> n, number w, string info)
```

This function creates a new hlist by packaging the list that begins at node n into a horizontal box. With only a single argument, this box is created using the natural width of it's components. In the three argument form, info must be either additional or exactly, and w is the additional (\hbox spread) or exact (\hbox to) width to be used.

Caveat: at this moment, there can be unexpected side-effects to this function, like updating some of the \marks and \inserts.

### 4.3.1.14 node.slide

```
<node> m = node.slide(<node> n)
```

Returns the last node of the node list that starts at n. As a side-effect, it also creates a reverse chain of prev pointers between nodes.

### 4.3.1.15 node.length

```
number i = node.length(<node> n)
number i = node.length(<node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at n. If m is also supplied it stops at m instead of at the end of the list. The node m is not counted.

### 4.3.1.16 node.count

```
number i = node.count(number id, <node> n)
number i = node.count(number id, <node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at n that have an matching id field. If m is also supplied, counting stops at m instead of at the end of the list. The node m is not counted.

This function also accept string id's.

### **4.3.1.17** node.traverse

```
<node> t = node.traverse(<node> n)
<node> t = node.traverse(<node> n, <node> m)
```

This is an iterator that loops over the node list that starts at n. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

### 4.3.1.18 node.traverse\_id

```
<node> t = node.traverse_id(number id, <node> n, <node> m)
<node> t = node.traverse id(number id, <node> n)
```

This is an iterator that loops over all the nodes in the list that starts at n that have a matching id field. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

This function also accept string id's.

### 4.3.1.19 node.remove

```
<node> head, current = node.remove(<node> head, <node> current)
```

This function removes the node current from the list following head. It is your responsibility to make sure it is really part of that list. The return values are the new head and current nodes. The returned current is the node in the calling argument, and is only passed back as a convenience (it's next field will be cleared). The returned head is more important, because if the function is called with current equal to head, it will be changed.

### 4.3.1.20 node.insert\_before

```
<node> head, new = node.insert_before(<node> head, <node> current, <node>
new)
```

This function inserts the node new before current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the

(potentially mutated) head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

### 4.3.1.21 node.insert\_after

```
<node> head, new = node.insert_after(<node> head, <node> current, <node>
new)
```

This function inserts the node new after current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

### 4.3.2 Attribute handling

Attributes appear as linked list of userdata objects in the attr field of individual nodes. They can be handled individually, but it much safer and more efficient to use the dedicated functions associated with them.

### 4.3.2.1 node.has\_attribute

```
number v = node.has_attribute(<node> n, number id)
number v = node.has_attribute(<node> n, number id, number val)
```

Tests if a node has the attribute with number id set. If val is also supplied, also tests if the value matches val. It returns the value, or, if no match is found, nil.

### 4.3.2.2 node.set\_attribute

```
node.set_attribute(<node> n, number id, number val)
```

Sets the attribute with number id to the value val. Duplicate assignments are ignored.

### 4.3.2.3 node.unset attribute

```
number v = node.unset_attribute(<node> n, number id, number val)
number v = node.unset attribute(<node> n, number id)
```

Unsets the attribute with number id. If val is also supplied, it will only perform this operation if the value matches val. Missing attributes or attribute-value pairs are ignored.

If the attribute was actually deleted, returns its old value. Otherwise, returns nil.

# 4.4 The texio library

This library takes care of the low-level I/O interface.

# 4.4.1 Printing functions

#### 4.4.1.1 texio.write

```
texio.write(string target, string s)
texio.write(string s)
```

Without the target argument, writes the string to the same location(s)  $T_EX$  writes messages to at this moment. If  $\$  writes in effect, it writes only to the log, otherwise it writes to the log and the terminal.

The optional target can be one of three possibilities: term, log or term and log.

### 4.4.1.2 tex.write\_nl

```
texio.write_nl(string target, string s)
texio.write_nl(string s)
```

Like texio.write, but make sure that the string s will appear at the beginning of a line. You can use an empty string if you only want to move to the next line.

# 4.5 The pdf library

This table contains the current h en v values that define the location on the output page. The values can be queried and set using scaled points as units.

```
pdf.v
pdf.h
```

The associated function calls are

```
pdf.setv(number n)
number n = pdf.getv()
pdf.seth(number n)
number n = pdf.geth()
```

It also holds a print function to write stuff to the *PDF* document, that can be used from within a \latelua argument. This function is not to be used inside \directlua unless you know *exactly* what you are doing.

### pdf.print

```
pdf.print(string s)
pdf.print(string type, string s)
```

The optional parameter can be used to mimic the behaviour of \pdfliteral: the type is direct or page.

# 4.6 The callback library

This library has functions that register, find and list callbacks.

The callback library is only available in LuA state zero (0).

```
callback.register(string callback_name,function callback_func)
callback.register(string callback_name,nil)
```

where the callback\_name is a predefined callback name, see below.

LUATEX internalizes the callback function in such a way that it does not matter if you redefine a function accidentally.

Callback assignments are always global. You can use the special value nil instead of a function for clearing the callback.

```
table info = callback.list()
```

The keys in the table are the known callback names, the value is a boolean where true means that the callback is currently set (active).

```
function f = callback.find(callback_name)
```

If the callback is not set, callback.find returns nil.

# 4.6.1 File discovery callbacks

### 4.6.1.1 find\_read\_file and find\_write\_file

You callback function should have the following conventions:

```
string actual_name = function (number id_number, string asked_name)
```

Arguments:

id\_number

This number is zero for the log or  $\in TEX$ s  $\in Text{read}$  or  $\in Text{write}$  the number is incremented by one, so  $\in Text{read}$ 0 becomes 1.

asked\_name

This is the user-supplied filename, as found by \input, \openin or \openout.

Return value:

actual\_name

This is the filename used. For the very first file that is read in by  $T_EX$ , you have to make sure you return an actual\_name that has an extension and that is suitable for use as jobname. If you don't, you will have to manually fix the name of the log file and output file after  $LVAT_EX$  is finished, and an eventual format filename will become mangled. That is because these file names depend on the jobname.

You have to return nil if the file cannot be found.

### 4.6.1.2 find\_font\_file

Your callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked\_name is an OTF or TFM font metrics file.

Return nil if the file cannot be found.

### 4.6.1.3 find\_output\_file

You callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked\_name is the PDF or DVI file for writing.

#### 4.6.1.4 find format file

You callback function should have the following conventions:

```
string actual name = function (string asked name)
```

The asked\_name is a format file for reading (the format file for writing is always opened in the current directory).

#### **4.6.1.5** find vf file

Like  $find_font_file$ , but for virtual fonts. This applies to both Aleph's over files and traditional Knuthian ver files.

### 4.6.1.6 find\_ocp\_file

Like find\_font\_file, but for ocp files.

### 4.6.1.7 find\_map\_file

Like find\_font\_file, but for map files.

### 4.6.1.8 find\_enc\_file

Like find\_font\_file, but for enc files.

### 4.6.1.9 find\_sfd\_file

Like find\_font\_file, but for subfont definition files.

### 4.6.1.10 find\_pk\_file

Like find\_font\_file, but for pk bitmap files. The argument name is a bit special in this case. It's form is

<base res>dpi/<fontname>.<actual res>pk

So you may be asked for 600dpi/manfnt.720pk. It is up to you to find a 'reasonable' bitmap file to go with that specification.

### 4.6.1.11 find\_data\_file

Like find\_font\_file, but for embedded files (\pdfobj file '...').

### 4.6.1.12 find\_opentype\_file

Like find\_font\_file, but for OpenType font files.

### 4.6.1.13 find\_truetype\_file and find\_type1\_file

You callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked\_name is a font file. This callback is called while LuaTeX is building its internal list of needed font files, so the actual timing may surprise you. Your return value is later fed back into the matching read file callback.

Strangely enough, find\_type1\_file is also used for OpenType (otf) fonts.

### 4.6.1.14 find\_image\_file

You callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked\_name is an image file. Your return value is used to open a file from the harddisk, so make sure you return something that is considered the name of a valid file by your operating system.

### 4.6.2 File reading callbacks

### 4.6.2.1 open\_read\_file

You callback function should have the following conventions:

```
table env = function (string file_name)
```

Argument:

file\_name

the filename returned by a previous find\_read\_file or the return value of kpse.find\_file() if there was no such callback defined.

Return value:

env

this is a table containing at least one required and one optional callback functions for this file. The required field is reader and the associated function will be called once for each new line to be read, the optional one is close that will be called once when LVATEX is done with the file

 $LUAT_EX$  never looks at the rest of the table, so you can use it to store your private per-file data. Both the callback functions will receive the table as their only argument.

### 4.6.2.1.1 reader

LUATEX will run this function whenever it needs a new input line from the file.

```
function(table env)
    return string line
end
```

Your function should return either a string or nil. The value nil signals that the end of file has occurred, and will make  $T_FX$  call the optional close function next.

#### **4.6.2.1.2** close

LUATEX will run this optional function when it decides to close the file.

```
function(table env)
    return
end
```

Your function should not return any value.

### 4.6.2.2 General file readers

There is a set of callbacks for the loading of binary data files. These all use the same interface:

```
function(string name)
    return boolean success, string data, number data_size
end
```

The name will normally be a full path name as it is returned by either one of the file discovery callbacks or the internal version of kpse.find\_file().

```
success
```

return false when a fatal error occured (e.g. when the file cannot be found, after all).

the bytes comprising the file.

data\_size

the length of the data, in bytes.

return an empty string and zero if the file was found but there was a reading problem.

The list of functions is:

```
read font file
                        This function is called when T_FX needs to read a ofm or tfm file.
read vf file
                        for virtual fonts.
read_ocp_file
                        for ocp files.
read map file
                        for map files.
read_enc_file
                        for encoding files.
read_sfd_file
                        for subfont definition files.
                        for pk bitmap files.
read_pk_file
read_data_file
                        for embedded files (\pdfobj file '...').
read_truetype_file
                       for TRUETYPE font files.
                        for TYPE1 font files.
read_type1_file
read_opentype_file for OPENTYPE font files.
```

## 4.6.3 Data processing callbacks

### 4.6.3.1 process\_input\_buffer

This callback allows you to change the contents of the line input buffer just before LUATEX actually starts looking at it.

```
function(string buffer)
    return string adjusted_buffer
end
```

If you return  $\mathtt{nil}$ ,  $\mathtt{LUATEX}$  will pretend like your callback never happened. You can gain a small amount of processing time from that.

### 4.6.3.2 token\_filter

This callback allows you to replace the way LUATEX fetches lexical tokens.

```
function()
    return table token
end
```

The calling convention for this callback is bit more complicated than for most other callbacks. The function should either return a *LuA* table representing a valid to-be-processed token or tokenlist, or something else like nil or an empty table.

If your *LuA* function does not return a table representing a valid token, it will be immediately called again, until it eventually does return a useful token or tokenlist (or until you reset the callback value to nil). See the description of token for some handy functions to be used in conjunction with this callback.

If your function returns a single usable token, then that token will be processed by LuaTEX immediately. If the function returns a token list (a table consisting of a list of consecutive token tables), then that list will be pushed to the input stack as completely new token list level, with it's token type set to 'inserted'. In either case, the returned token(s) will not be fed back into the callback function.

# 4.6.4 Node list processing callbacks

The description of nodes and node lists is in chapter 6.

### 4.6.4.1 buildpage\_filter

This callback is called whenever LuATEX is ready to move stuff to the main vertical list. You can use this callback to do specialized manipulation of the page building stage like imposition or column balancing.

```
function(<node> head, string extrainfo)
    return true | false | <node> newhead
end
```

As for all the callbacks that deal with nodes, the return value can be one of three things:

- boolean true signals succesful processing
- node signals that the 'head' node should be replaced by this node
- boolean false signals that the 'head' node list should be ignored and flushed from memory

The string extrainfo gives some additional information about what  $T_EX$ s state is with respect to the `current page'. The possible values are:

value	explanation
alignment	a (partial) alignment is being added
box	a typeset box is being added
begin_of_par	the beginning of a new paragraph
vmode_par	\par was found in vertical mode
hmode_par	\par was found in horizontal mode
insert	an insert is added
penalty	a penalty (in vertical mode)
before_display	immediately before a display starts
after_display	a display is finished

### 4.6.4.2 pre\_linebreak\_filter

This callback is called just before  $LuaT_EX$  starts converting a list of nodes into a stack of \hboxes. The removal of a possible final skip and the subsequent insertion of \parfillskip has not happened yet at that moment.

```
function(<node> head, string groupcode, int glyph_count)
    return true | false | <node> newhead
end
```

The string called groupcode identifies the nodelist's context within  $T_EX$ s processing. The range of possibilities is given in the table below, but not all of those can actually appear in pre\_linebreak\_filter, some are for the hpack\_filter and vpack\_filter callbacks that will be explained in the next two paragraphs.

value	explanation
hbox	\hbox in horizontal mode
adjusted_hbox	\hbox in vertical mode
vbox	\vbox
vtop	\vtop
align	\halign or \valign
disc	discretionaries

insert packaging an insert \vcenter vcenter \localleftbox or \localrightbox local box split\_off top of a \vsplit split keep remainder of a \vsplit preamble alignment preamble align set alignment cell fin\_row alignment row

### 4.6.4.3 hpack filter

This callback is called when  $T_EX$  is ready to start boxing some horizontal mode material. Math items are ignored at the moment.

The packtype is either additional or exactly. If additional, then the size is a \hbox spread ... argument. If exactly, then the size is a \hbox to .... In both cases, the number is in scaled points.

### 4.6.4.4 vpack\_filter

This callback is called when  $T_EX$  is ready to start boxing some vertical mode material. Math displays are ignored at the moment.

This function is very similar to the  $hpack_filter$ . Besides the fact that it is called at different moments, there is an extra variable that matches  $T_EX$ 's \maxdepth setting, but there is no glyph count.

### 4.6.4.5 pre\_output\_filter

This callback is called when  $T_EX$  is ready to start boxing the box 255 for \output.

# 4.6.5 Information reporting callbacks

### 4.6.5.1 start\_run

```
function()
```

Replaces the code that prints *LUATEX*'s banner

### 4.6.5.2 stop\_run

#### function()

Replaces the code that prints LuATEX's statistics and 'output written to' messages.

### 4.6.5.3 start\_page\_number

#### function()

Replaces the code that prints the [ and the page number at the begin of \shipout. This callback will also override the printing of box information that normally takes place when \tracingoutput is positive.

### 4.6.5.4 stop\_page\_number

#### function()

Replaces the code that prints the ] at the end of \shipout

### 4.6.5.5 show\_error\_hook

```
function()
return
```

end

This callback is run from inside the  $T_EX$  error function, and the idea is to allow you to do some extra reporting on top of what  $T_EX$  already does (none of the normal actions are removed). You may find some of the values in the status table useful.

#### message

is the formal error message  $T_EX$  has given to the user (the line after the !!) indicator

is either a filename (when it is a string) or a location indicator (a number) that can means lots of different things like a token list id or a \read number.

is the current line number

This is an investigative item for 'testing the water' only. The final goal is the total replacement of  $T_EX$ 's error handling routines, but that needs lots of adjustments in the web source because  $T_EX$  deals with errors in a somewhat haphazard fashion. This is why the exact definition of indicator is not given here.

### 4.6.6 Font-related callbacks

### 4.6.6.1 define\_font

function(string name, number size, number id) return table font end

The string name is the filename part of the font specification, as given by the user.

The number **size** is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the font table that is to be returned is explained in chapter 5. That table is saved internally, so you can put extra fields in the table for your later LUA code to use.

# 4.7 The lua library

This library contains two read-only items:

#### 4.7.1 Variables

number n = lua.id

This returns the id number of the instance.

```
string s = lua.version
```

This returns a  $LUAT_EX$  version identifier string. The value is currently lua.version, but it is soon to be replaced by something more elaborate.

## 4.7.2 LUA bytecode registers

LUA registers can be used to communicate LUA functions across LUA states. The accepted values for assignments are functions and nil. Likewise, the retrieved value is either a function or nil.

```
lua.bytecode[n] = function () .. end
lua.bytecode[n]()
```

The contents of the lua.bytecode array is stored inside the format file as actual LUA bytecode, so it can also be used to preload lua code.

The associated function calls are

```
function f = lua.getbytecode(number n)
lua.setbytecode(number n, function f)
```

# 4.8 The kpse library

#### kpse.find file 4.8.1

The most important function in the library is find\_file:

```
string f = kpse.find_file(string filename)
string f = kpse.find_file(string filename, string ftype)
string f = kpse.find file(string filename, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, number dpi)
```

#### Arguments:

#### filename

the name of the file you want to find, with or without extension.

maps to the -format argument of KPSEWHICH. The supported ftype values are the same as the ones supported by the standalone kpsewhich program:

```
'gf'
                                              'ls-R'
'pk'
                                              'fmt'
'bitmap font'
                                              'map'
'tfm'
                                              'mem'
'afm'
                                              'mf'
'base'
                                              'mfpool'
'bib'
                                              'mft'
'bst'
                                              'mp'
'cnf'
                                              'mppool'
```

```
'MetaPost support'
                                          'ist'
'ocp'
                                          'truetype fonts'
'ofm'
                                          'type42 fonts'
                                          'web2c files'
'opl'
'otp'
                                          'other text files'
'ovf'
                                          'other binary files'
'qvo'
                                          'misc fonts'
'graphic/figure'
                                          'web'
'tex'
                                          'cweb'
'TeX system documentation'
                                          'enc files'
'texpool'
                                          'cmap files'
                                          'subfont definition files'
'TeX system sources'
'PostScript header'
                                          'opentype fonts'
'Troff fonts'
                                          'pdftex config'
'type1 fonts'
                                          'lig files'
'vf'
                                          'texmfscripts'
'dvips config'
```

The default type is tex.

mustexist

is similar to  $\kappa_{PSEWHICH}$ 's -must-exist, and the default is false. If you specify true (or a non-zero integer), then the  $\kappa_{PSE}$  library will search the disk as well as the ls-R databases. dpi

This is used for the size argument of the formats pk, gf, and bitmap font.

# 4.8.2 kpse.set\_program\_name

Sets the KPATHSEA executable (and optionally program) name

```
kpse.set_program_name(string name)
kpse.set_program_name(string name, string progname)
```

The second argument controls the use of the 'dotted' values in the texmf.cnf configuration file, and defaults to the first argument.

# 4.8.3 kpse.init\_prog

Extra initialization for programs that need to generate bitmap fonts.

```
kpse.init_prog(string prefix, number base_dpi, string mfmode)
kpse.init_prog(string prefix, number base_dpi, string mfmode, string fall-back)
```

# 4.8.4 kpse.readable\_file

Test if an (absolute) file name is a readable file

```
string f = kpse.readable_file(string name)
```

The return value is the actual absolute filename you should use, because the disk name is not always the same as the requested name, due to aliases and system-specific handling under e.g. <code>MSDOS</code>.

Returns nil if the file does not exist or is not readable.

# 4.8.5 kpse.expand\_path

```
Like kpsewhich's -expand-path:
```

```
string r = kpse.expand_path(string s)
```

# 4.8.6 kpse.expand\_var

```
Like kpsewhich's -expand-var:
```

```
string r = kpse.expand_var(string s)
```

# 4.8.7 kpse.expand\_braces

```
Like kpsewhich's -expand-braces:
```

```
string r = kpse.expand_braces(string s)
```

# 4.8.8 kpse.var\_value

```
Like kpsewhich's -var-value:
```

```
string r = kpse.var value(string s)
```

# 4.9 The status library

This contains a number of run-time configuration items that you may find useful in message reporting, as well as an iterator function that gets all of the names and values as a table.

```
table info = status.list()
```

The keys in the table are the known items, the value is the current value.

Almost all of the values in status are fetched through a metatable at run-time whenever they are accessed, so you cannot use pairs on status, but you can use pairs on info, of course.

If you do not need the full list, you can also ask for a single item by using it's name as an index into status.

The current list is:

key explanation
pdf\_gone written PDF bytes

pdf\_ptr not yet written PDF bytes

dvi\_gone written *DVI* bytes

var\_used variable (one-word) memory in use
dyn\_used token (multi-word) memory in use

init\_str\_ptr number of *INITEX* strings max\_strings maximum allowed strings

var\_mem\_maxnumber of allocated words for nodesfix\_mem\_maxnumber of allocated words for tokensfix\_mem\_endmaximum number of used tokenscs\_countnumber of control sequences

hash\_size size of hash
hash\_extra extra allowed hash
font\_ptr number of active fonts

jobname	string		if no input file name was given on the com- mandline, this key will be tested first instead of simply giving up

# 4.11 The font library

The font library provides the interface into the internals of the font system, and also it contains helper functions to load traditional  $T_EX$  font metrics formats. Other font loading functionality is provided by the fontforge library that will be discussed in the next section.

# 4.11.1 Loading a TFM file

```
table fnt = font.read_tfm(string name, number s)
```

The number is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the metrics font table that is returned is explained in chapter 5.

# 4.11.2 Loading a VF file

```
table vf_fnt = font.read_vf(string name, number s)
```

The meaning of the number s, and the format of the returned table is the silimar to the read\_tfm() function.

# 4.11.3 The fonts array

The whole table of  $T_EX$  fonts is accessible from lua using a virtual array.

```
font.fonts[n] = { ... }
table f = font.fonts[n]
```

See chapter 5 for the structure of the tables. Because this is a virtual array, you cannot call pairs on it, but see below for the font.each iterator.

The two metatable functions implementing the virtual array are:

```
table f = font.getfont(number n)
font.setfont(number n, table f)
```

Also note the following: assignments can only be made to fonts that have already been defined in *TEX*, but have not been accessed *at all* since that definition. This limits the usability of the write access to font.fonts quite a lot, a less stringent ruleset will likely be implemented later.

# 4.11.4 Checking a font's status

You can test for the status of a font by calling this function:

```
boolean f = font.frozen(number n)
```

The return value is one of true (unassignable), false (can be changed) or nil (not a valid font at all).

# 4.11.5 Defining a font directly

You can define your own font into font.fonts

```
number i = font.define(table f)
```

The return value is the internal id number of the defined font (the index into font.fonts). If the font creation fails, an error is raised. The table is a font structure, as explained in chapter 5.

# 4.11.6 Currently active font

```
number i = font.current();
```

This is the currently used font number.

### 4.11.7 Maximum font id

```
number i = font.max();
```

This is the largest used index in font.fonts.

### 4.11.8 Iterating over all fonts

```
for i,v in font.each() do
   ...
end
```

This is an iterator over each of the defined  $T_EX$  fonts. The first returned value is the index in font.fonts, the second the font itself, as a lua table. The indices are listed incrementally, but they do not always form an array of consecutive numbers: in some cases there can be holes in the sequence.

# 4.12 The fontforge library

# 4.12.1 Getting quick information on a font

```
local info = fontforge.info('filename')
```

This function returns either nil, or a table, or an array of small tables (in the case of a TrueType collection). The returned table(s) will contain six fairly interesting information items from the font(s) defined by the file:

```
type
                       explanation
key
fontname
                string the 'PostScript' name of the font
fullname
                string
                       The formal name of the font
familyname
                string
                       The family name this font belongs to
weight
                string
                       A string indicating the color value of the font
                       The internal font version
version
                string
                       The slant angle
italicangle float
```

Getting information through this function is (sometimes much) more efficient than loading the font properly, and is therefore handy when you want to create a dictionary of available fonts based on a directory contents.

# 4.12.2 Loading an OPENTYPE or TRUETYPE file

If you want to use an *OpenType* font, you have to get the metric information from somewhere. Using the fontforge library, the basic way to get that information is thus:

```
function load_font (filename)
  local metrics = nil
  local font = fontforge.open(filename)
  if font then
    metrics = fontforge.to_table(font)
    fontforge.close(font)
  end
  return metrics
end

myfont = load_font('/opt/tex/texmf/fonts/data/arial.ttf')
The main function call is
local f = fontforge.open('filename')
```

For TRUETYPE collections (when filename ends in 'ttc'), you have to use a second string argument to specify which font you want from the collection. Use one of the fullname strings that are returned by fontforge.info for that.

```
local f = fontforge.open('filename','fullname')
```

The font file is parsed and partially interpreted by the font loading routines from FontForge. The file format can be *OpenType*, *TrueType*, *TrueType*, *Collection*, CFF, or *Type1*.

There are a few advantages to this approach compared to reading the actual font file ourselves:

- The font is automatically re-encoded, so that the metrics table for TRUETYPE and OPENTYPE fonts is using UNICODE for the character indices.
- Many features are pre-processed into a format that is easier to handle than just the bare tables would be.
- PostScript-based OpenType fonts do not store the character height and depth in the font file, so the character boundingbox has to be calculated in some way.
- In the future, it may be interesting to allow *LUA* scripts access to the font program itself, perhaps even creating or changing the font.

# 4.12.3 Applying a 'feature file'

```
You can apply a `feature file' to a loaded font:
```

```
fontforge.apply_featurefile(f,'filename')
```

A `feature file' is a textual representation of the features in an OpenType font. See http://www.adobe.com/devnet/opentype/afdko/topic\_feature\_file\_syntax.html and http://fontforge.sourceforge.net/featurefile.html for a more detailed description of feature files.

# 4.12.4 Applying an 'afm file'

You can apply a 'afm file' to a loaded font:

```
fontforge.apply_afmfile(f,'filename')
```

An 'afm file' is a textual representation of (some of) the metainformation in a Type 1 font. See http://www.adobe.com/devnet/font/pdfs/5004.AFM\_Spec.pdf for more information about afm files.

Note: if you fontforge.open() a PFB file named font.pfb, the library will automatically search for, and apply, font.afm if it exists in the same directory as font.pfb. In that case, there is no need for an explicit call to apply\_afmfile().

# 4.13 Fontforge font tables

The top-level keys in the returned table are (the explanations in this part of the documentation is not yet finished):

key	type	explanation
table_version	number	indicates the metrics version
fontname	string	PostScript font name
fullname	string	official font name
familyname	string	family name
weight	string	weight indicator
copyright	string	copyright information
filename	string	the file name
version	string	font version
italicangle	float	slant angle
units_per_em	number	1000 for <i>PostScript</i> -based fonts, usually 2048 for
		TrueType
ascent	number	height of ascender in units_per_em
descent	number	depth of descender in units_per_em
upos	float	
uwidth	float	
vertical_origin	number	
uniqueid	number	
glyphcnt	number	number of included glyphs
glyphs	array	
glyphmax	number	maximum used index the glyphs array
hasvmetrics	number	

order2 set to 1 for TRUETYPE splines, 0 otherwise strokedfont number weight width slope only number head\_optimized\_for\_cleartype number uni\_interp unset, none, adobe, greek, japanese, trad\_chinese, enum simp\_chinese, korean, ams the file name, as supplied by the user origname string table map table private xuid string pfminfo table names table cidinfo table subfonts array cidmaster array commments string anchor\_classes table ttf tables table kerns table vkerns table texdata table lookups table table gpos gsub table chosenname string macstyle number fondname string design\_size number fontstyle\_id number fontstyle\_name table design\_range\_bottom number number design\_range\_top strokewidth float mark\_classes array mark class names array creationtime number modificationtime number os2 version number

### 1 Glyph items

The glyphs is an array containing the per-character information (quite a few of these are only present if nonzero).

```
explanation
key
                  type
name
                  string
                           the glyph name
unicodeenc
                  number
                           unicode code point, or -1
boundingbox
                           array of four numbers
                  array
width
                           (only for horizontal fonts)
                  number
vwidth
                  number
                           (only for vertical fonts)
                           (only if nonzero)
lsidebearing
                  number
glyph_class
                  number
                           (only if nonzero)

comment
                  string
```

The kerns and vkerns are linear arrays of small hashes:

key	type	explanation
char	string	
off	number	
lookup	strina	

The lookups is a hash based on lookup subtable names, with the value of each key inside that a linear array of small hashes:

```
key type explanation

type enum position, pair, substitution, alternate, multiple, ligature, lcaret, kerning, vkerning, anchors, contextpos, contextsub, chainpos, chainsub, reversesub, max, kernback, vkernback specification table extra data
```

For the first seven values of type, there can be additional sub-information, stored in the sub-table specification:

value	type	explanation
position	table	a table of the offset_specs type
pair	table	one string: paired, and an array of one or two offset_specs tables: offsets
substitution	table	one string: variant
alternate	table	one string: components
multiple	table	one string: components

```
ligature table two strings: components, char
lcaret array linear array of numbers
```

Tables for offset\_specs contain up to four number-valued fields: x (a horizontal offset), y (a vertical offset), h (an advance width correction) and v (an advance height correction).

The ligatures is a linear array of small hashes:

```
keytypeexplanationligtableuses the same substructure as a single possub itemcharstringcomponentsarraylinear array of named componentsccntnumber
```

The anchor table is indexed by a string signifying the anchor type, which is one of

```
key type explanation
mark table placement mark
basechar table mark for attaching combining items to a base char
baselig table mark for attaching combining items to a ligature
basemark table generic mark for attaching combining items to connect to
centry table cursive entry point
cexit table cursive exit point
```

The content of these is an short array of defined anchors, with the entry keys being the anchor names. For all except baselig, the value is a single table with this definition:

For baselig, the value is a small array of such anchor sets sets, one for each constituent item of the ligature.

For clarification, an anchor table could for example look like this :

```
['anchor']={
    ['basemark']={
        ['Anchor-7']={ ['x']=170, ['y']=1080 }
    },
    ['mark']={
        ['Anchor-1'] ={ ['x']=160, ['y']=810 },
        ['Anchor-4']= { ['x']=160, ['y']=800 }
    },
    ['baselig']={
        [1] = { ['Anchor-2'] ={ ['x']=160, ['y']=650 } },
        [2] = { ['Anchor-2']= { ['x']=460, ['y']=640 } }
```

```
}
},
```

# 2 map table

The top-level map is a list of encoding mappings. Each of those is a table itself.

key	type	explanation
enccount	number	
encmax	number	
backmax	number	
remap	table	
map	array	non-linear array of mappings
backmap	array	non-linear array of backward mappings
enc	table	

The remap table is very small:

key	type	explanation
firstenc	number	
lastenc	number	
infont	number	

The enc table is a bit more verbose:

key	type	explanation
enc_name	string	•
char_cnt	number	
char_max	number	
unicode	array	of <i>Unicode</i> position numbers
psnames	array	·
builtin	number	3 31
hidden	number	
only_1byte	number	
has_1byte	number	
has_2byte	number	
is_unicodebmp	number	(only if nonzero)
is_unicodefull	number	(only if nonzero)
is_custom	number	(only if nonzero)
is_original	number	(only if nonzero)
is_compact	number	(only if nonzero)
is_japanese	number	(only if nonzero)
is_korean	number	(only if nonzero)
is_tradchinese	number	(only if nonzero)
is_simplechinese	number	(only if nonzero)

low\_page number high\_page number iconv\_name string iso\_2022\_escape string

### 3 private table

This is the font's private *PostScript* dictionary, if any. Keys and values are both strings.

### 4 cidinfo table

key	type	explanation
registry	string	
ordering	string	
supplement	number	
version	number	

### 5 pfminfo table

The pfminfo table contains most of the OS/2 information:

key	type	explanation
pfmset	number	
winascent_add	number	
windescent_add	number	
hheadascent_add	number	
hheaddescent_add	number	
typoascent_add	number	
typodescent_add	number	
subsuper_set	number	
panose_set	number	
hheadset	number	
vheadset	number	
pfmfamily	number	
weight	number	
width	number	
avgwidth	number	
firstchar	number	
lastchar	number	
fstype	number	
linegap	number	
vlinegap	number	

hhead_ascent	number
hhead_descent	number
hhead_descent	number
os2_typoascent	number
os2_typodescent	number
os2_typolinegap	number
os2_winascent	number
os2_windescent	number
os2_subxsize	number
os2_subysize	number
os2_subxoff	number
os2_subyoff	number
os2_supxsize	number
os2_supysize	number
os2_supxoff	number
os2_supyoff	number
os2_strikeysize	number
os2_strikeypos	number
os2_family_class	number
os2_xheight	number
os2_capheight	number
os2_defaultchar	number
os2_breakchar	number
os2_vendor	string
panose	table

The panose subtable has exactly 10 string keys:

key	type	explanation
familytype	string	Values as in the <i>OpenType</i> font specification: Any, No Fit, Text and
		Display, Script, Decorative, Pictorial
serifstyle	string	See the OpenType font specification for values
weight	string	id.
proportion	string	id.
contrast	string	id.
${\tt strokevariation}$	string	id.
armstyle	string	id.
letterform	string	id.
midline	string	id.
xheight	strina	id.

### 6 names table

Each item has two top-level keys:

key type explanation

lang string language for this entry

table names

The names keys are the actual TRUETYPE name strings. The possible keys are:

explanation

copyright family subfamily uniqueid fullname

postscriptname

trademark

version

manufacturer

designer

descriptor

venderurl

designerurl

license

licenseurl

idontknow

preffamilyname

prefmodifiers

compatfull

sampletext

cidfindfontname

### 7 anchor\_classes table

The anchor\_classes classes:

key type explanation

A descriptive id of this anchor class namestring

lookup string

One of 'mark', 'mkmk', 'curs', 'mklg' type string

### 8 gpos table

Th gpos table has one array entry for each lookup.

key explanation type

One of 'gpos\_single', 'gpos\_pair', 'gpos\_cursive', 'gpos\_mark2base', 'gpos\_mark2ligature', type string

'gpos\_mark2mark', 'gpos\_context', 'gpos\_contextchain'

flags table
name string
features array
subtables array

The flags table has a true value for each of the lookup flags that is actually set:

key type explanation
r21 boolean
ignorebaseglyphs boolean
ignorecombiningmarks boolean

The features table has:

key type explanation
tag string
scripts table
ismax number (only if true)

The scripts table within features has:

key type explanation
script string
langs array of strings

The subtables table has:

key type explanation namestring suffix string (only if used) anchor\_classes number (only if used) vertical kerning number (only if used) kernclass table (only if used)

The kernclass with subtables table has:

keytypeexplanationfirstsarray of stringssecondsarray of stringslookupstringassociated lookupoffsetsarray of numbers

### 9 qsub table

This has identical layout to the gpos table, except for the type:

```
key
       type
               explanation
type string
               One of 'gsub_single', 'gsub_multiple', 'gsub_alternate', 'gsub_ligature', 'gsub_context',
               'gsub_contextchain', 'gsub_reversecontextchain'
```

### 10 ttf\_tables table

key	type	explanation
tag	string	
len	number	
maxlen	number	
data	number	

#### 11 kerns table

Substructure is identical to the per-glyph subtable.

### 12 vkerns table

Substructure is identical to the per-glyph subtable.

### 13 texdata table

key	type	explanation		
type	string	unset, text, math, mathext		
params	array	22 font numeric parameters		

### 14 lookups table

Top-level lookups is quite different from the ones at character level. The keys in this hash are strings, the values the actual lookups, represented as dictionary tables.

key	type	explanation
type	number	
format	enum	One of 'glyphs', 'class', 'coverage', 'reversecoverage'
tag	string	
current_class	array	
before_class	array	
after_class	array	
rules	array	an array of rule items

Rule items have one common item and one specialized item:

key type explanation

lookups array A linear array of lookup names
glyph array Only if the parent's format is 'glyph'
class only if the parent's format is 'glyph'
coverage array Only if the parent's format is 'glyph'

reversecoverage array Only if the parent's format is 'glyph'

A glyph table is:

key type explanation

names string back string fore string

A class table is:

key type explanation
current array of numbers
before array of numbers
after array of numbers

coverage:

key type explanation
current array of strings
before array of strings
after array of strings

reversecoverage:

keytypeexplanationcurrentarrayof stringsbeforearrayof stringsafterarrayof strings

replacements string

# 5 Font structure

All  $T_EX$  fonts are represented to LVA code as tables, and internally as C structures. All keys in the table below are saved in the internal font structure if they are present in the table returned by the define\_font callback, or if they result from the normal  $T_FM/V_F$  reading routines if there is no define\_font callback defined.

The column 'from vF' means that this key will be created by the font.read\_vf() routine, 'from TFM' means that the key will be created by the font.read\_tfm() routine, and 'used' means whether or not the  $LvAT_FX$  engine itself will do something with the key.

The top-level keys in the table are as follows:

key	from vf	from tfm	used	value type	description
name	yes	yes	yes	string	metric (file) name
area	no	yes	yes	string	(directory)location, typically empty
used	no	yes	yes	boolean	used already? (initial: false)
characters	yes	yes	yes	table	the defined glyphs of this font
checksum	yes	yes	no	number	default: 0
designsize	no	yes	yes	number	expected size (default: 655360 == 10pt)
direction	no	yes	yes	number	default: 0 (LTR)
encodingbytes	no	no	yes	number	default: depends on format
encodingname	no	no	yes	string	encoding name
fonts	yes	no	yes	table	locally used fonts
fullname	no	no	yes	string	actual (PostScript) name
header	yes	no	no	string	header comments, if any
hyphenchar	no	no	yes	number	default: TeX's \hyphenchar
parameters	no	yes	yes	hash	default: 7 parameters, all zero
size	no	yes	yes	number	loaded (at) size. (default: same as designsize)
skewchar	no	no	yes	number	default: TeX's \skewchar
type	yes	no	yes	string	basic type of this font
format	no	no	yes	string	disk format type
embedding	no	no	yes	string	PDF inclusion
filename	no	no	yes	string	disk file name

The key name is always required.

The key **used** is set by the engine when a font is actively in use, this makes sure that the font's definition is written to the output file (*DVI* or *PDF*). The *TFM* reader sets it to false.

The direction is a number signalling the 'normal' direction for this font. There are sixteen possibilities:

number	meaning	number	meaning
0	LT	8	TT
1	LL	9	TL

2	LB	10	TB
3	LR	11	TR
4	RT	12	ВТ
5	RL	13	BL
6	RB	14	BB
7	RR	15	BR

These are *OMEGA*-style direction abbreviations: the first character indicates the 'first' edge of the character glyphs (the edge that is seen first in the writing direction), the second the 'top' side.

The parameters is a hash with mixed key types. There are seven possible string keys, as well as a number of integer indices (these start from 8 up). The seven strings are actually used instead of the bottom seven indices, because that gives a nicer user interface.

The names and their internal remapping:

name	internal remapped number
slant	1
space	2
space_stretch	3
space_shrink	4
x_height	5
quad	6
extra_space	7

The keys type, format, embedding, fullname and filename are used to embed *OPENTYPE* fonts in the result *PDE*.

The characters table is a list of character hashes indexed by integer number. The number is the 'internal code'  $T_FX$  knows this character by.

Two very special string indexes can be used also: left\_boundary is a virtual character whose ligatures and kerns are used to handle word boundary processing. right\_boundary is similar but not actually used for anything (yet!).

Other index keys are ignored.

Each character hash itself is a hash. For example, here is the character 'f' (decimal 102) in the font cmr10 at 10 points:

```
[102] = {
  ['width'] = 200250
  ['height'] = 455111,
  ['depth'] = 0,
  ['italic'] = 50973,
  ['kerns'] = {
     [63] = 50973,
     [93] = 50973,
     [39] = 50973,
```

```
[33] = 50973,
     [41] = 50973
  },
  ['ligatures'] = {
    [102] = {
       ['char'] = 11,
       ['type'] = 0
    },
    [108] = {
       ['char'] = 13,
       ['type'] = 0
    },
    [105] = {
       ['char'] = 12,
       ['type'] = 0
    }
  },
}
```

The following top-level keys can be present inside a character hash:

key	from vf	from tfm	used	value type	description
width	yes	yes	yes	number	character's width, in sp (default 0)
height	no	yes	yes	number	character's height, in sp (default 0)
depth	no	yes	yes	number	character's depth, in sp (default 0)
italic	no	yes	yes	number	character's italic correction, in sp (default zero)
next	no	yes	yes	number	the 'next larger' character index
extensible	no	yes	yes	table	the constituent parts of an extensible recipe
kerns	no	yes	yes	table	kerning information
ligatures	no	yes	yes	table	ligaturing information
commands	yes	no	yes	array	virtual font commands
name	no	no	no	string	the character ( <i>PostScript</i> ) name
index	no	no	yes	number	the ( <i>OpenType</i> or <i>TrueType</i> ) font glyph index
used	no	yes	yes	boolean	typeset already (default: false)?

The presence of extensible will overrule next, if that is also present.

The extensible table is very simple:

```
keytypedescriptiontopnumber'top' character indexmidnumber'middle' character indexbotnumber'bottom' character indexrepnumber'repeatable' character index
```

The kerns table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right\_boundary), with the values the kerning to be applied, in scaled points.

The ligatures table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right\_boundary), with the values being yet another small hash, with two fields:

# key type description type number the type of this ligature command, default 0 char number the character index of the resultant ligature

The char field in a ligature is required.

The type field inside a ligature is the numerical or string value of one of the eight possible ligature types supported by  $T_EX$ . When  $T_EX$  inserts a new ligature, it puts the new glyph in the middle of the left and right glyphs. The original left and right glyphs can optionally be retained, and when at least one of them is kept, it is also possible to move the new 'insertion point' forward one or two places. The glyph that ends up to the right of the insertion point will become the next 'left'.

textual (Knuth)	number	string	result
l + r =: n	0	=:	n
$l + r =: \mid n$	1	=:	nr
l + r =: n	2	=:	ln
l + r =   n	3	=:	lnr
l + r =:  > n	5	=:  >	n r
l + r =:> n	6	=:>	l∣n
l + r =   > n	7	=: >	l nr
l + r = > n	11	=: >>	ln r

The default value is 0, and can be left out. That signifies a 'normal' ligature where the ligature replaces both original glyphs. In this table the | indicates the final insertion point.

The commands array is explained below.

# 5.1 Real fonts

Whether or not a *T<sub>E</sub>X* font is a 'real' font that should be written to the *PDF* document is decided by the type value in the top-level font structure. If the value is real, then this is a proper font, and the inclusion mechanism will attempt to add the needed font object definitions to the *PDF*.

Values for type:

# value description real this is a base font virtual this is a virtual font

The actions to be taken depend on a number of different variables:

- Whether the used font fits in an 8-bit encoding scheme or not
- The type of the disk font file
- The level of embedding requested

A font that uses anything other than an 8-bit encoding vector has to be written to the *PDF* in a different way.

The rule is: if the font table has encodingbytes set to 2, then this is a wide font, in all other cases it isn't. The value 2 is the default for *OpenType* and *TrueType* fonts loaded via *Lua*. For *Type1* fonts, you have to set encodingbytes to 2 explicitly. For *PK* bitmap fonts, wide font encoding is not supported at all.

If no special care is needed, LuATEX currently falls back to the mapfile-based solution used by PDFTEX and DVIPS. This behaviour will be removed in the future, when the existing code becomes integrated in the new subsystem.

But if this is a 'wide' font, then the new subsystem kicks in, and some extra fields have to be present in the font structure. In this case, *LuATFX* does not use a map file at all.

The extra fields are: format, embedding, fullname, cidinfo (as explained above), filename, and the index key in the separate characters.

Values for format are:

```
valuedescriptiontype1this is a PostScript Type1 fonttype3this is a bitmapped (PK) fonttruetypethis is a TrueType or TrueType-based OpenType fontopentupethis is a PostScript-based OpenType font
```

(type3 fonts are provided for backward compatibility only, and do not support the new wide encoding options.)

Values for embedding are:

```
value description
no don't embed the font at all
subset include and atttempt to subset the font
full include this font in it's entirety
```

At the moment, subset only works for non-cid fonts. These are essentially treated as if full was specified.

It is not possible to artificially modify the transformation matrix for the font at the moment.

The other fields are used as follows: The fullname will be the PostScript/PDF font name. The cidinfo will be used as the character set (the CID /Ordering and /Registry keys). The filename points to the actual font file. If you include the full path in the filename or if the file is in the local directory, LuaTeX will run a little bit more efficient because it will not have to re-run the find\_xxx\_file callback in that case.

Be careful: when mixing old and new fonts in one document, it is possible to create *PostScript* name clashes that can result in printing errors. When this happens, you have to change the fullname of the font.

Typeset strings are written out in a wide format using 2 bytes per glyph, using the index key in the character information as value. The overall effect is like having an encoding based on numbers instead of traditional (PostScript) name-based reencoding. The way to get the correct index numbers for Type1 fonts is by loading the font via fontforge.open; use the table indices as index fields.

This type of reencoding means that there is no longer a clear connection between the text in your input file and the strings in the output *PDF* file. Dealing with this is high on the agenda.

## 5.2 Virtual fonts

You have to take the following steps if you want LuaTEX to treat the returned table from define\_font as a virtual font:

- Set the top-level key type to virtual.
- Make sure there is at least one valid entry in fonts (see below)
- Give a commands array to every character (see below)

The presence of the toplevel type key with the specific value virtual will trigger handling of the rest of the special virtual font fields in the table, but the mere existence of 'type' is enough to prevent LuaTeX from looking for a virtual font on its own.

Therefore, this also works 'in reverse': if you are absolutely certain that a font is not a virtual font, assigning the value base or real to type will inhibit LUATEX from looking for a virtual font file, thereby saving you a disk search.

The fonts is another Lua array. The values are one- or two-key hashes themselves, each entry indicating one of the base fonts in a virtual font. An example makes this easy to understand

says that the first referenced font (index 1) in this virtual font is ptrmr8a loaded at 10pt, and the second is psyr loaded at a little over 9pt. The third one is previously defined font that is known to LVATEX as fontid '38'.

The array index numbers are used by the character command definitions that are part of each character.

The commands array is a hash here each item is another small array, with first entry representing a command and the extra items the parameters to that command. The allowed commands and their arguments are:

```
command name arguments arg type description
font 1 number select a new font from the local fonts table
```

char	1	number	typeset this character number from the current
node	1	node	output this node (list), and move right
slot	2	number	a shortcut for a font, char set
push	0		save current position
nop	0		do nothing
pop	0		pop position
rule	2	2 numbers	output a rule $w * h$ , and move right
down	1	number	move down on the page
right	1	number	move right on the page
special	1	string	output a \special command
comment	any	any	the rest of the command is ignored

Here is a rather elaborate glyph commands example:

```
commands = {
  {'push'},
                                -- remember where we are
  {'right', 5000},
                                -- move right about 0.08pt
  {'font', 1},
                                -- select the fonts[1] entry
  {'char', 97},
                                -- place character 97 (a)
  {'pop'},
                                 -- go all the way back
  {'down', -200000},
                                 -- move *up* about 3pt
                                -- switch to red color
  {'special', 'pdf: 1 0 0 rg'}
  {'rule', 500000, 20000}
                                 -- draw a bar
  {'special','pdf: 0 g'}
                                 -- back to black
}
```

The default value for font is always 1, for each character anew. If the virtual font is essentially only a re-encoding, then you do usually not have create an explicit 'font' entry.

Regardless of the amount of movement you create within the commands, the output pointer will always move by exactly the width as given in the width key of the character hash, after running the commands.

#### 5.2.1 Artificial fonts

Even in a 'real' font, there can be virtual characters. When LuaTEX encounters a commands field inside a character when it becomes time to typeset the character, it will interpret the commands, just like for a true virtual character. In this case, if you have created no 'fonts' array, then the default and only 'base' font is taken to be the current font itself. In practise, this means that you can create virtual duplicates of existing characters.

Note: this feature does *not* work the other way around. There can not be 'real' characters in a virtual font!

Finally, here is a plain  $T_EX$  input file with a virtual font demonstration:

```
\directlua0 {
  callback.register('define font',
    function (name, size)
      if name == 'cmr10-red' then
        f = font.read_tfm('cmr10',size)
        f.name = 'cmr10-red'
        f.type = 'virtual'
        f.fonts = {{ name = 'cmr10', size = size }}
        for i,v in pairs(f.characters) do
          if (string.char(i)):find('[tacohanshartmut]') then
             v.commands = {
               {'special','pdf: 1 0 0 rg'},
               {'char',i},
               {'special','pdf: 0 g'},
          else
             v.commands = {{'char',i}}
          end
        end
      else
        f = font.read_tfm(name, size)
      return f
    end
  )
}
\font\myfont = cmr10-red at 10pt \myfont This is a line of text \par
\font\myfontx= cmr10 at 10pt \myfontx Here is another line of text \par
```

# 6 Nodes

## 6.1 LUA node representation

 $T_EX$ s nodes are represented in LvA as userdata object with a variable set of fields. In the following syntax tables, such the type of such a userdata object is represented as  $\langle node \rangle$ .

The current return value of node.types() is: vlist (1), rule (2), ins (3), mark (4), adjust (5), disc (7), whatsit (8), math (9), glue (10), kern (11), penalty (12), unset (13), style (14), choice (15), ord (16), op (17), bin (18), rel (19), open (20), close (21), punct (22), inner (23), radical (24), fraction (25), under (26), over (27), accent (28), vcenter (29), left (30), right (31), action (39), margin\_kern (40), glyph (41), attribute (42), glue\_spec (43), attribute\_list (44), hlist (0), but as already mentioned, the math and alignment nodes in this list are not supported at the moment. The useful list is described in the next sections.

## 6.1.1 Auxiliary items

A few node-typed userdata objects do not occur in the 'normal' list of nodes, but can be pointed to from within that list. They are not quite the same as regular nodes, but it is easier for the library routines to treat them as if they were.

#### 6.1.1.1 qlue\_spec items

Skips are about the only type of data objects in traditional  $T_EX$  that are not a simple value. The structure that represents the glue components of a skip is called a glue\_spec, and it has the following accessible fields:

key	type	explanation
width	number	
stretch	number	
stretch_order	number	
shrink	number	
shrink order	number	

These objects are reference counted, so there is actually an extra field named ref\_count as well. This item type will likely disappear in the near future, and the glue fields themselves will become part of the nodes referencing glue items.

#### 6.1.1.2 attribute\_list items

The newly introduced attribute registers are non-trivial, because the value that is attached to a node is essentially a sparse array of key-value pairs.

It is generally easiest to deal with attributes by using the dedicated functions in the node library, but for completeness, here is the low-level interface:

field type explanation
next <node> pointer to the first attribute

There are no extra fields, this kind of item is only used as a head pointer for attribute items, making them easier to handle.

A normal node's attribute field will point to an item of type attribute\_list, and the next field in that item will point to the first defined 'attribute' item, whose next will point to the second 'attribute' item, etc.

#### 6.1.1.3 attribute item

Valid fields:

ref\_count

field type explanation
next <node> pointer to the next attribute
number number the attribute type id
value number the attribute value

#### 6.1.1.4 action item

Valid fields: action\_type, named\_id, action\_id, file, new\_window, data, ref\_count These are a special kind of item that only appears inside pdf start link objects.

field type explanation
action\_type number
action\_id number or string
named\_id number
file string
new\_window number
data string

#### 6.1.2 Main text nodes

number

These are the nodes that comprise actual typesetting commands.

A few fields are present in all nodes regardless of their type, these are:

field type explanation
next <node> The next node in a list, or nil

```
id number The node's type (id) number subtype number The node subtype identifier
```

The subtype is sometimes just a stub entry. Not all nodes actually use the subtype, but this way you can be sure that all nodes accept it as a valid field name, and that is often handy in node list traversal. In the following tables next and id are not explicitly mentioned.

Besides these three fields, almost all nodes also have an attr field, and there is a also field called prev. That last field is always present, but only initialized on explicit request: when the function node.slide() is called, it will set up the prev fields to be a backwards pointer in the argument node list.

#### 6.1.2.1 hlist nodes

Valid fields: attr, width, depth, height, dir, shift, glue\_order, glue\_sign, glue\_set, list

field	type	explanation
subtype	number	unused
attr	<node></node>	The head of the associated attribute list
width	number	
height	number	
depth	number	
shift	number	a displacement perpendicular to the character progression direction
glue_order	number	a number in the range 0—4, indicating the glue order
glue_set	number	the calculated glue ratio
glue_sign	number	
list	<node></node>	the body of this list
dir	number	the direction of this box

#### **6.1.2.2** vlist nodes

Valid fields: As for hlist, except that 'shift' is a displacement perpendicular to the line progression direction.

### 6.1.2.3 rule nodes

Valid fields: attr, width, depth, height, dir

field	type	explanation
subtype	number	unused
attr	<node></node>	
width	number	rule size. The special value $-1073741824$ is used for 'running' glue dimensions
height	number	11

depth number ''

dir number the direction of this rule

#### 6.1.2.4 ins nodes

Valid fields: attr, cost, depth, height, top\_skip, list

explanation field type subtype number the insertion class <node> attrcost number the penalty associated with this insert height number depth number the body of this insert list <node> top\_skip <node> a pointer to the \splittopskip qlue spec

#### **6.1.2.5** mark nodes

Valid fields: attr, class, mark

field type explanation subtype number unused

attr <node>

class number the mark class

mark table a table representing a token list

### 6.1.2.6 adjust nodes

Valid fields: attr, list

field type explanation

subtype number 0 = normal, 1 = 'pre'

attr <node>

list <node> adjusted material

### 6.1.2.7 disc nodes

Valid fields: attr, pre, post, replace

field type explanation subtype number unused

attr <node>

#### **6.1.2.8** math nodes

Valid fields: attr, surround

field type explanation subtype number 0 = 'on', 1 = 'off' attr < node > surround number width of the \mathsurround kern

### 6.1.2.9 qlue nodes

Valid fields: attr, spec, leader

### 6.1.2.10 kern nodes

Valid fields: attr, kern

field type explanation
subtype number  $0 = \text{from font}, 1 = \text{from } \text{ or } \ \ 2 = \text{from } \text{ accent}$ attr <node>
kern number

### 6.1.2.11 penalty nodes

Valid fields: attr, penalty

field type explanation
subtype number not used
attr <node>
penalty number

#### 6.1.2.12 qlyph nodes

Valid fields: attr, char, font, components, xoffset, yoffset

```
field
                          explanation
                tupe
                          0 = \text{normal}, 1 = \text{ligature}, 2 = \text{leftboundary ligature}, 3 = \text{rightboundary}
subtype
                number
                          ligature
attr
                <node>
char
                number
font
                number
components
               <node>
                          pointer to ligature components
                number
xoffset
yoffset
               number
```

#### 6.1.2.13 margin\_kern nodes

```
Valid fields: attr, width, glyph
```

field	type	explanation
subtype	number	0 = left side, 1 = right side
attr	<node></node>	
width	number	
glyph	<node></node>	

### 6.1.3 whatsit nodes

Whatsit nodes come in many subtypes, that you can ask for my running node.whatsits(): write (1), close (2), special (3), language (4), local\_par (6), dir (7), pdf\_literal (8), pdf\_refobj (10), pdf\_refxform (12), pdf\_refximage (14), pdf\_annot (15), pdf\_start\_link (16), pdf\_end\_link (17), pdf\_dest (19), pdf\_thread (20), pdf\_start\_thread (21), pdf\_end\_thread (22), pdf\_save\_pos (23), late\_lua (35), close\_lua (36), user\_defined (43), pdf\_restore (42), pdf\_colorstack (39), pdf\_setmatrix (40), pdf\_save (41), open (0),

#### **6.1.3.1 open nodes**

Valid fields: attr, stream, name, area, ext

field	type	explanation
attr	<node></node>	
stream	number	<i>TEX</i> 's stream id number
name	string	file name
ext	string	file extension
area	string	file area

### 6.1.3.2 write nodes

Valid fields: attr, stream, data

field type explanation

attr <node>

stream number *TEX*'s stream id number

data table a table representing the token list to be written

#### 6.1.3.3 close nodes

Valid fields: attr, stream

field type explanation

attr <node>

stream number  $T_FX$ 's stream id number

### 6.1.3.4 special nodes

Valid fields: attr, data

field type explanation

attr <node>

data string the \special information

#### 6.1.3.5 language nodes

Valid fields: attr, lang, left, right

field type explanation

attr <node>

lang number language id number

left number value of \lefthyphenmin
right number value of \righthyphenmin

### 6.1.3.6 local\_par nodes

Valid fields: attr, pen\_inter, pen\_broken, dir, box\_left, box\_left\_width, box\_right, box\_right\_width

field type explanation

attr <node>

pen\_broken number broken penalty dir number the direction of this par box left <node> the \localleftbox box\_left\_width width of the \localleftbox number <node> box right the \localrightbox box\_right\_width number width of the \localrightbox

#### 6.1.3.7 dir nodes

Valid fields: attr, dir, level, dvi\_ptr, dvi\_h

field tupe explanation attr <node> dir number the direction level number nesting level of this direction whatsit dvi ptr number a saved dvi buffer byte offset dir\_h number a saved dvi position

#### 6.1.3.8 pdf\_literal nodes

Valid fields: attr, mode, data

field type explanation
attr <node>
mode number the 'mode' setting of this literal
data string the \pdfliteral information

### 6.1.3.9 pdf\_refobj nodes

Valid fields: attr, objnum

field type explanation
attr <node>
objnum number the referenced PDF object number

### 6.1.3.10 pdf\_refxform nodes

Valid fields: attr, width, height, depth, objnum.

field type explanation
attr <node>
width number

```
height number
depth number
objnum number the referenced PDF object number
```

Be aware that pdf\_refxform nodes have dimensions that are used by LUATEX.

### 6.1.3.11 pdf\_refximage nodes

Valid fields: attr, width, height, depth, objnum

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
objnum	number	the referenced <i>PDF</i> object number

Be aware that pdf\_refximage nodes have dimensions that are used by LUATEX.

### 6.1.3.12 pdf\_annot nodes

Valid fields: attr, width, height, depth, objnum, data

```
field type explanation
attr <node>
width number
height number
depth number
objnum number the referenced PDF object number
data string the annotation data
```

## 6.1.3.13 pdf\_start\_link nodes

Valid fields: attr, width, height, depth, objnum, link\_attr, action

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
objnum	number	the referenced PDF object number
link_attr	table	the link attribute token list
action	<node></node>	the action to perform

## 6.1.3.14 pdf\_end\_link nodes

Valid fields: attr

field type explanation

attr <node>

## 6.1.3.15 pdf\_dest nodes

Valid fields: attr, width, height, depth, named\_id, dest\_id, dest\_type, xyz\_zoom, objnum

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
$named_id$	number	is the dest_id a string value?
${\tt dest\_id}$	number or string	the destination id
dest_type	number	type of destination
xyz_zoom	number	
objnum	number	the PDF object number

### 6.1.3.16 pdf\_thread nodes

Valid fields: attr, width, height, depth, named\_id, thread\_id, thread\_attr

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
named_id	number	is the tread_id a string value?
tread_id	number or string	the thread id
${\tt thread\_attr}$	number	extra thread information

## $6.1.3.17 \hspace{0.2cm} pdf\_start\_thread \hspace{0.2cm} nodes$

Valid fields: attr, width, height, depth, named\_id, thread\_id, thread\_attr

field	type	explanation
attr	<node></node>	
width	number	
height	number	

depth number

named\_id number is the tread\_id a string value?

thread\_attr number extra thread information

### 6.1.3.18 pdf\_end\_thread nodes

Valid fields: attr

field type explanation

attr <node>

### 6.1.3.19 pdf\_save\_pos nodes

Valid fields: attr

field type explanation

attr <node>

### 6.1.3.20 late\_lua nodes

Valid fields: attr, reg, data

field type explanation

attr <node>

reg number *LuA* state id number data string data to execute

#### 6.1.3.21 close\_lua nodes

Valid fields: attr, reg

field type explanation

attr <node>

reg number LUA state id number

### 6.1.3.22 pdf\_colorstack nodes

Valid fields: attr, stack, cmd, data

field type explanation

attr <node>

stack number colorstack id number
cmd number command to execute
data string data

### 6.1.3.23 pdf\_setmatrix nodes

Valid fields: attr, data

field type explanation
attr <node>
data string data

## 6.1.3.24 pdf\_save nodes

Valid fields: attr

field type explanation
attr <node>

## 6.1.3.25 pdf\_restore nodes

Valid fields: attr

field type explanation
attr <node>

## 6.1.3.26 user\_defined nodes

Valid fields: attr, user\_id, type, value

field type explanation
attr <node>
user\_id number id number
type number type of the value
value number
string
<node>
table

## 7 Modifications

Besides the expected changes caused by new functionality, there are a number of not-so-expected changes. These are sometimes a side-effect of a new (conflicting) feature, or, more often than not, a change necessary to clean up the internal interfaces.

# 7.1 Changes from T<sub>E</sub>X 3.141592

- There is no pool file, all strings are embedded during compilation.
- plus 1 fill11 does not generate an error. The extra 'l' is simply typeset.
- The \endlinechar can be either added (values 0 or more), or not (negative values). If it is added, the character is always decimal 13 a/k/a ^M a/k/a carriage return (This change may be temporary).

# 7.2 Changes from $\varepsilon$ -TEX 2.2

- The  $\varepsilon$ - $T_EX$  functionality is always present and enabled (but see below about  $T_EXXET$ ), so the prepended asterisk or -etex switch for  $INIT_EX$  is not needed.
- TFXXET is not present, so the primitives

\TeXXeTstate \beginR \beginL \endR

\endL

are missing

- Some of the tracing information that is output by  $\varepsilon$ - $T_EX$ 's \tracingassigns and \tracingrestores is not there.
- Register management in  $LVAT_EX$  uses the ALEPH model, so the maximum value is 65535 and the implementation uses a flat array instead of the mixed flatCsparse model from  $\varepsilon$ - $T_EX$ .

# 7.3 Changes from PDFT<sub>E</sub>X 1.40

- The (experimental) support for snap nodes has been removed, because it much more natural to build this functionality on top of node processing and attributes. The associated primitives that are now gone are: \pdfsnaprefpoint, \pdfsnapy, and \pdfsnapycomp.
- A number of 'utility functions' is removed:

\pdfelapsedtime \pdffilemoddate \pdfresettimer
\pdfescapehex \pdffilesize \pdfshellescape
\pdfescapename \pdflastmatch \pdfstrcmp
\pdfescapestring \pdfmatch \pdfunescapehex
\pdffiledump \pdfmdfivesum

• A few other experimental primitives are also provided without the extra pdf prefix, so they can also be called like this:

\primitive \ifabsnum \ifprimitive \ifabsdim

- The definitions for new didot and new cicero are patched.
- The \pdfprimitive is bugfixed.
- The \pdftexversion is set to 200.

# 7.4 Changes from ALEPH RC4

• The input translations from ALEPH are not implemented, the related primitives are not available

\DefaultInputMode \DefaultInputTranslation \noDefaultInputTranslation \noDefaultInputTranslation

\noInputMode \noInputTranslation \InputTranslation

\DefaultOutputMode \DefaultOutputTranslation \noDefaultOutputMode \noDefaultOutputTranslation

\noOutputMode \noOutputTranslation \OutputTranslation

- A small series of bounds checking fixes to \ocp and \ocplist has been added to prevent the system from crashing due to array indexes running out of bounds.
- The \hoffset bug when \pagedir TRT is fixed, removing the need for an explicit fix to \hoffset
- A bug causing \fam to fail for family numbers above 15 is fixed.
- Some bits of *ALEPH* assumed 0 and null were identical. This resulted for instance in a bug that sometimes caused an eternal loop when trying to \show a box.
- A fair amount of minor bugs are fixed as well, most of these related to \tracingcommands output.
- The number of possible fonts, ocps and ocplists is smaller than their maximum *ALEPH* value (around 5000 fonts and 30000 ocps / ocplists).
- The internal function scan\_dir() has been renamed to scan\_direction() to prevent a naming clash.
- The ^^ notation can come in five and six item repetitions also, to insert characters that do not fit in the BMP.

# 7.5 Changes from standard WEB2C

- There is no mltex
- There is no enctex
- The following commandline switches are silently ignored, even in non-LuA mode:

```
-8bit
-translate-file=TCXNAME
-mltex
-enc
-etex
```

- \openout whatsits are not written to the log file.
- Some of the so-called web2c extensions are hard to set up in non-KPSE mode because texmf.cnf is not read: shell-escape is off (but that is not a problem because of LUA's os.execute), and the paranoia checks on openin and openout do not happen (however, it is easy for a LUA script to do this itself by overloading io.open).

#### 8 Implementation notes

## 8.1 Primitives overlap

The primitives

\pdfpagewidth \pagewidth \pdfpageheight \pageheight \fontcharwd \charwd \fontcharht \charht \fontchardp \chardp \fontcharic \charic

are all aliases of each other.

# Memory allocation

The single internal memory heap that traditional  $T_FX$  used for tokens and nodes is split into two separate arrays. Each of these will grow dynamically when needed.

The texmf.cnf settings related to main memory are no longer used (these are: main memory, mem\_bot, extra\_mem\_top and extra\_mem\_bot). 'Out of main memory' errors can still occur, but the limiting factor is now the amount of RAM in your system, not a predefined limit.

Also, the memory (de)allocation routines for nodes are completely rewritten. The relevant code now lives in the C file luanode.c, and basically uses a dozen or so avail lists instead of a doublylinked model. At this moment, speed is still a little suboptimal because separate helper structures are maintained for debugging checks.

Because of the split into two arrays and the resulting differences in the data structures, some of the Pascal WEB macros have been duplicated. For instance, there are now vlink and vinfo as well as link and info. All access to the variable memory array is now hidden behind a macro called vmem.

The implementation of the growth of two arrays (via reallocation) introduces a potential pitfall: the memory arrays should never be used as the left hand side of a statement that can modify the array in question.

The input line buffer and pool size are now also reallocated when needed, and the texmf.cnf settings buf size and pool size are silently ignored.

# 8.3 Sparse arrays

The \mathcode, \delcode, \catcode, \sfcode, \lccode and \uccode tables are now sparse arrays that are implemented in C. They are no longer part of the  $T_FX$  'equivalence table' and because

each had 1.1 million entries with a few memory words each, this makes a major difference in memory usage.

These assignments do not yet show up when using the etex tracing routines \tracingassigns and \tracingrestores (code simply not written yet)

A side-effect of the current implementation is that \global is now more expensive in terms of processing than non-global assignments.

See mathcodes.c and textcodes.c if you are interested in the details.

Also, the glyph ids within a font are now managed by means of a sparse array and glyph ids can go up to index  $2^{21} - 1$ .

# Simple single-character csnames

Single-character commands are no longer treated aspecially in the internals, they are stored in the hash just like the multiletter csnames.

The code that displays control sequences explicitly checks if the length is one when it has to decide whether or not to add a trailing space.

#### **Compressed format** 8.5

The format is passed through zlib, allowing it to shrink to roughly half of the size it would have had in uncompressed form. This takes a bit more CPU cycles but much less disk I/O, so it should still be faster.

#### Binary file reading 8.6

All of the internal code is changed in such a way that if one of the read\_xxx\_file callbacks is not set, then the file is read by a C function using basically the same convention as the callback: a single read into a buffer big enough to hold the entire file contents. While this uses more memory than the previous code (that mostly used getc calls), it can be quite a bit faster (depending on your I/O subsystem).

# 9 Known bugs and limitations

The bugs below are going to be fixed eventually.

The top ones will be fixed soon, but in the later items either the actual problem is hard to find, or the code that causes the bug is going to be replaced by a new subsystem soon anyway, or it may not be worth the hassle and the limitations will eventually be documented.

- Seaching of directly-generated PDF documents that use wide fonts is impossible, due to explicit referencing (by LUATEX) of font glyph indices without a ToUnicode map being included.
- Hyphenation can only deal with the Base Multilingual Plane (BMP)
- tex.print() and tex.sprint() do not work if \directlua is used in an *oTP* file (in the output of an expression rule).
- Handling of attributes in math mode is not complete. The data structures in math mode are quite different from those in text mode, so this will take some extra effort to implement correctly.
- When used inside \directlua, pdf.print() should create a literal node instead of flushing immediately.
- At the moment, only characters in plane 0 and plane 1 can be assigned catcode 13 (i.e. turned into active characters). This is a temporary measure to reduce the memory requirements of LvaTeX. In general, LvaTeX's memory footprint is a bit larger that we would like (with plain.fmt preloaded it needs about 55MB).
- Not all of *ALEPH*'s direction commands are handled properly in *PDF* mode, and especially the vertical scripts support is missing almost completely (only TRT and TLT are routinely tested).
- Letter spacing (\letterspacefont) is currently non-functional due to massive changes in the virtual font handling. This functionality may actually be removed completely in the future, because it is straightforward to set up letterspacing using the LuA 'define\_font' interface.
- Node pointers are not always checked for validity, so if you make a mistake in the node list processing, LuATEX may about with an assertion error.

## **10 TODO**

On top of the 'normal' extensions that are planned, there are some more specific small feature requests. Whether these will all be included is not certain yet, (and new requests are welcome).

- Implement the TEX primitive \dimension, cf. \number
- Change the LUA table tex.dimen to accept and return float values instead of strings
- Do something about \withoutpt and/or a new register type \real?
- Create callback for the automatic creation of missing characters in fonts
- Implement the *T<sub>F</sub>X* primitive \htdp?
- Do boxes with dual baselines.
- A way to (re?)calculate the width of a \vbox, taking only the natural width of the included items into account.
- Make the number of the output box configurable.
- Complete the attributes in math and switch all the nodes to a double-linked list.
- Finish the interface from Lua to TEX's internals, specially the hash and equivalence table (a small subpart is implementing \csname lookups for tex.box access).
- Integrate the various PDFTEX extended font codes for hz en protruding into the font table
- Use of Type1C for embedded PostScript font subsets.
- Support font reencoding of 8-bit fonts via char index.
- Attempt to parse OFM level 0 fonts that are masquerading as level 1.
- Add line numbers and input context information to the lua errors
