#### Introduction 1

This book will eventually become the reference manual of LuaTFX. At the moment, it simply reports the behaviour of the executable matching the snapshot or beta release date in the title page.

Features may come and go. The current version of LuaTFX is not meant for production and users cannot depend on stability, nor on functionality staying the same.

Nothing is considered stable just yet. This manual therefore simply reflects the current state of the executable. Absolutely nothing on the following pages is set in stone. When the need arises, anything can (and will) be changed without prior notice.

If you are not willing to deal with this situation, you should wait for the stable version. Currently we expect the first release with (some) fixed interfaces to be available sometime in the autumn of 2008. Full stabilization will not happen soon, the TODO list is still very large.

LuaTFX consists of a number of interrelated but (still) distinguishable parts:

- pdfT<sub>F</sub>X version 1.40.9
- Aleph RC4 (from the TFXLive repository)
- Lua 5.1.2 (+ coco 1.1.3)
- dedicated Lua libraries
- various TFX extensions
- parts of FontForge 2008.11.17
- a still experimental version of the MetaPost library
- newly written compiled source code to glue it all together

Neither Aleph's I/O translation processes, nor tcx files, nor encTEX can be used, these encoding-related functions are superseded by a Lua-based solution (reader callbacks). Also, some experimental pdfTFX features are removed. These can be implemented in Lua instead.

# Basic TEX enhancements

# **Version information**

There are three new primitives to test the version of LuaTFX:

<pre>primitive \luatexversion</pre>	explanation a combination of major and minor number, as in pdfTEX; the current current value is 36
\luatexrevision \luatexdatestamp	the revision number, as in pdfT $_{E}X$ ; the current value is $0$ a combination of the local date and hour when the current executable was compiled, the syntax is identical to $\label{luatexrevision}$ ; the value for the executable that generated this document is $2009032014$ .

The official LuaTFX version is defined follows:

- The major version is the integer result of \luatexversion divided by 100. The primitive is and 'internal variable', so you may need to prefix it use with \the depending on the context.
- The minor version is the two-digit result of \luatexversion modulo 100.
- The revision is the given by \luatexrevision. This primitive expands to a positive integer.
- The full version number consists of the major version, minor version and revision, separated by dots.

Note that the \luatexdatestamp depends on both the compilation time and compilation place of the current executable, it is defined in terms of the local time. The purpose of this primitive is solely to be an aid in the development process, do not use it for anything besides debugging.

# 2.2 UNICODE text support

Text input and output is now considered to be Unicode text, so input characters can use the full range of Unicode  $(2^{20} + 2^{16} - 1 = 10FFFF = 1114111)$ .

Later chapters will talk of characters and glyphs. Although these are not the interchangeable, they are closely related. During typesetting, a character is always converted to a suitable graphic representation of that character in a specific font. However, while processing a list of to-be-typeset nodes, its contents may still be seen as a character. Inside LuaTFX there is not yet a clear separation between the two concepts. Until this is implemented, please do not be too harsh on us if we make errors in the usage of the terms.

Note: for now, it only makes sense to use values above the base plane ("OxFFFF) for \mathcode and \catcode assignments, since the hyphenation patterns are still limited to max. 16-bit values, so the other commands will not know what to do with those high values.

A few primitives are affected by this, all in a similar fashion: each of them has to accommodate for a larger range of acceptable numbers. For instance, \char now accepts values between 0 and 1114111.

This should not be a problem for well-behaved input files, but it could create incompatibilities for input that would have generated an error when processed by older  $T_EX$ -based engines. The maximum number of allocations is "10FFFF or  $2^{20} + 2^{16} - 1$  (21 bits). The maximum value that can be assigned are:

primitive	bits	hex	numeric
\char	21	10FFFF	$2^{20} + 2^{16} - 1$
\chardef	21	10FFFF	$2^{20} + 2^{16} - 1$
\lccode	21	10FFFF	$2^{20} + 2^{16} - 1$
\uccode	21	10FFFF	$2^{20} + 2^{16} - 1$
\sfcode	15	7FFF	$2^{15} - 1$
\catcode	4	F	$2^4 - 1$

As far as the core engine is concerned, all input and output to text files is utf-8 encoded. Input files can be pre-processed using the reader callback. This will be explained in a later chapter.

Output in byte-sized chunks can be achieved by using characters just outside of the valid Unicode range, starting at the value 1.114.112 (0x110000). When the times comes to print a character c > =1.114.112, LuaTEX will actually print the single byte corresponding to c = 1.114.112.

Output to the terminal uses  $^$  notation for the lower control range (c < 32), with the exception of  $^$ I,  $^$ J and  $^$ M. These are considered 'safe' and therefore printed as-is.

Normalization of the Unicode input can be handled by a macro package during callback processing (this will be explained in **section 4.8.2**).

# 2.3 Extended tables

All traditional TEX and  $\varepsilon$ -TEX registers can be 16 bit numbers as in Aleph. The affected commands are:

\count	\countdef	\unhbox	\ht
\dimen	\dimendef	\unvbox	\dp
\skip	\skipdef	\сору	\setbox
\muskip	\muskipdef	\unhcopy	\vsplit
\marks	\toksdef	\unvcopy	
\toks	\box	\wd	

The glyph properties (like \efcode) introduced in pdfTEX that deal with font expansion (hz) and character protruding are also 16 bit. Because font memory management has been rewritten, these character properties are no longer shared among fonts instances that originate from the same metric file

# 2.4 Attribute registers

Attributes are a completely new concept in LuaTEX. Syntactically, they behave a lot like counters: attributes obey TEX's nesting stack and can be used after  $\t$  etc. just like the normal  $\t$  registers.

```
\attribute (16-bit number) (optional equals) (31-bit number)
\attributedef \langle csname \rangle \langle optional equals \rangle \langle 16-bit number \rangle
```

Conceptually, an attribute is either 'set' or 'unset'. Set attributes can only have values of 0 or more, otherwise they are considered unset and automatically remapped to an special negative value meaning 'unset' (currently that value is -1, but please test on negativity, not on a specific value). All attributes start out in the 'unset' state (in iniTFX).

Attributes can be used as extra counter values, but their usefulness comes mostly from the fact that the numbers and values of all 'set' attributes are attached to all nodes created in their scope. These can then be queried from any Lua code that deals with node processing. Future versions of LuaTFX will probably be using specific negative attribute ids for internal use. Further information about how to use attributes for node list processing from Lua is given in chapter 8.

#### 2.4.1 Box attributes

Nodes typically receive the list of attributes that is in effect when they are created. This moment can be quite asynchronous. For example: in paragraph building, the individual line boxes are created after the \par command has been processed, so they will receive the list of attributes that is in effect then, not the attributes that were in effect in, say, the first or third line of the paragraph.

Similar situations happen in LuaTFX regularly. A few of the more obvious problematic cases are dealt with: the attributes for nodes that are created during hyphenation and ligaturing borrow their attributes from their surrounding glyphs, and it is possible to influence box attributes directly.

When you assemble a box in a register, the attributes of the nodes contained in the box are unchanged when such a box is placed, unboxed, or copied. In this respect attributes act the same as characters that have been converted to references to glyphs in fonts. For instance, when you use attributes to implement color support, each node carries information about its color. In that case, unless you implement mechanisms that deal with it, applying a color to already boxed material will have no effect. Keep in mind that this incompatibility is mostly due to the fact that specials and literals are a more unnatural approach to colors than attributes.

Many other inserted nodes, like the nodes resulting from math mode and alignments, are processed 'out of order', and will have the attributes that are in effect at the precise moment of creation (which is often later than expected). This area needs studying, and is in fact one of the reasons for a beta at this moment.

It is possible to fine-tune the list of attributes that are applied to a hbox, vbox or vtop by the use of the keyword attr. An example:

```
\attribute2=5
\setbox0=\hbox {Hello}
\setbox2=\hbox attr1=12 attr2=-1{Hello}
```

This will set the attribute list of box 2 to 1 = 12, and the attributes of box 0 will be 2 = 5. As you can see, assigning a negative value causes an attribute to be ignored.

The attr keyword(s) should come before a to or spread, if that is also specified.

# 2.5 LUA related primitives

In order to merge Lua code with TFX input, a few new primitives are needed.

#### 2.5.1 \directlua

The primitive \directlua is used to execute Lua code immediately. The syntax is

```
\directlua \( \text \) \directlua name \( \text \) \directlua \( \text \) \directlua \( \text \) \directlua \( \text \) \directlua \( \text \)
```

The last (general text) is expanded fully, and then fed into the Lua interpreter. After reading and expansion has been applied to the (general text), the resulting token list is converted to a string as if it was displayed using \the\toks. On the Lua side, each \directlua block is treated as a separate chunk. In such a chunk you can use the local directive to keep your variables from interfering with those used by the macro package.

The conversion from and to a token list means that you normally can not use Lua line comments (starting with --) within the argument, as there typically will be only one 'line', so that comment will then run on until the end of the input. You will either need to use  $T_EX$ -style line comments (starting with %), or change the  $T_FX$  category codes locally. Another possibility is to say:

```
\begingroup
\endlinechar=10
\directlua ...
\endgroup
```

Then Lua line comments can be used, since TFX does not replace line endings with spaces.

The name  $\langle general\ text \rangle$  specifies the name of the Lua chunk, mainly shown in the stack backtrace of error messages created by Lua code. The  $\langle general\ text \rangle$  is expanded fully, thus macros can be used to generate the chunk name, i.e.

```
\directlua name{\jobname:\the\inputlineno} ...
```

to include the name of the input file as well as the input line into the chunk name.

Likewise, the  $\langle 16\text{-bit number} \rangle$  designates a name of a Lua chunk, but in this case the name will be taken from the lua.name array (see the documentation of the lua table further in this manual)

The chunk name should not start with a @, or it will be displayed as a file name (this is a quirk in the current Lua implementation).

The \directlua command is expandable: the results of the Lua code become effective immediately. As an example, the following input:

```
$\pi = \directlua{tex.print(math.pi)}$
```

will result in

```
\pi = 3.1415926535898
```

Because the (general text) is a chunk, the normal Lua error handling is triggered if there is a problem in the included code. The Lua error messages should be clear enough, but the contextual information is still pretty bad. Typically, you will only see the line number of the right brace at the end of the code.

While on the subject of errors: some of the things you can do inside Lua code can break up LuaTFX pretty bad. If you are not careful while working with the node list interface, you may even end up with assertion errors from within the T<sub>F</sub>X portion of the executable.

#### 2.5.2 \latelua

\latelua stores Lua code in a whatsit that will be processed inside the output routine. Its intended use is a cross between \pdfliteral and \write. Within the Lua code, you can print pdf statements directly to the pdf file via tex.print, or you can write to other output streams via texio.write or simply using lua's I/O routines.

```
\latelua \( \text \)
\latelua name \( \text \) \( \text \)
\latelua \langle 16-bit number \rangle \langle general text \rangle
```

Expansion of macros etcetera in the final <general text> is delayed until just before the whatsit is executed (like in \write). With regard to PDF output stream \latelua behaves as \pdfliteral page.

The name (general text) and (16-bit number) behave in the same way as they do for \directlua

# 2.5.3 \luaescapestring

This primitive converts a TFX token sequence so that it can be safely used as the contents of a Lua string: embedded backslashes, double and single quotes, and newlines and carriage returns are escaped. This is done by prepending an extra token consisting of a backslash with category code 12, and for the line endings, converting them to  ${\tt n}$  and  ${\tt r}$  respectively. The token sequence is fully expanded.

```
\luaescapestring \( \text \)
```

Most often, this command is not actually the best way to deal with the differences between the TEX and Lua. In very short bits of Lua code it is often not needed, and for longer stretches of Lua code it is easier to keep the code in a separate file and load it using Lua's dofile:

```
\directlua { dofile('mysetups.lua')}
```

# 2.6 New $\varepsilon$ -TEX primitives

#### 2.6.1 \clearmarks

This primitive clears a marks class completely, resetting all three connected mark texts to empty.

```
\clearmarks \langle 16-bit number \rangle
```

# 2.6.2 \noligs and \nokerns

These primitives prohibit ligature and kerning insertion at the time when the initial node list is built by LuaTEX's main control loop. They are part of a temporary trick and will be removed in the near future. For now, you need to enable these primitives when you want to do node list processing of 'characters', where TEX's normal processing would get in the way.

```
\noligs \langle integer \\
\nokerns \langle integer \rangle
```

These primitives can now be implemented by overloading the ligature building and kerning functions, i.e. by assigning dummy functions to their associated callbacks.

#### 2.6.3 \formatname

\formatname's syntax is identical to \jobname.

In iniTEX, the expansion is empty. Otherwise, the expansion is the value that  $\jobname$  had during the iniTEX run that dumped the currently loaded format.

#### 2.6.4 \scantextokens

The syntax of \scantextokens is identical to \scantokens. This primitive is a slightly adapted version of  $\varepsilon$ -T<sub>F</sub>X's \scantokens. The differences are:

- The last (and usually only) line does not have a \endlinechar appended
- \scantextokens never raises an EOF error, and it does not execute \everyeof tokens.
- The '... while end of file ...' error tests are not executed, allowing the expansion to end on a different grouping level or while a conditional is still incomplete.

#### 2.6.5 Catcode tables

Catcode tables are a new feature that allows you to switch to a predefined catcode regime in a single statement. You can have a practically unlimited number of different tables.

The subsystem is backward compatible: if you never use the following commands, your document will not notice any difference in behavior compared to traditional TEX.

The contents of each catcode table is independent from any other catcode tables, and their contents is stored and retrieved from the format file.

#### 2.6.5.1 \catcodetable

```
\catcodetable \langle 16-bit number \rangle
```

The \catcodetable switches to a different catcode table. Such a table has to be previously created using one of the two primitives below, or it has to be zero. Table zero is initialized by iniTFX.

#### 2.6.5.2 \initcatcodetable

```
\initcatcodetable (16-bit number)
```

The \initcatcodetable creates a new table with catcodes identical to those defined by iniTFX:

```
0
                           escape
5
                                            (this name may change)
                   return
                           car_ret
    ^^@
9
                   null
                           ignore
10 <space>
                   space
                           spacer
11
    a - z
                           letter
11 \quad A - Z
                           letter
                           other
12
    everything else
14
                           comment
15
   ^^?
                   delete
                           invalid_char
```

The new catcode table is allocated globally: it will not go away after the current group has ended. If the supplied number is identical to the currently active table, an error is raised.

#### 2.6.5.3 \savecatcodetable

```
\savecatcodetable \langle 16-bit number \rangle
```

\savecatcodetable copies the current set of catcodes to a new table with the requested number. The definitions in this new table are all treated as if they were made in the outermost level.

The new table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

# 2.6.6 \suppressfontnotfounderror

\suppressfontnotfounderror = 1

If this new integer parameter is non-zero, then LuaTEX will not complain about font metrics that are not found. Instead it will silently skip the font assignment, making the requested csname for the font  $\infty$  equal to  $\infty$  to that it can be tested against that without bothering the user.

# 2.6.7 \suppresslongerror

```
\suppresslongerror = 1
```

If this new integer parameter is non-zero, then LuaTEX will not complain about \par commands encountered in contexts where that is normally prohibitited (most prominently in the arguments of non-long macros).

# 2.6.8 \suppressifcsnameerror

```
\suppressifcsnameerror = 1
```

If this new integer parameter is non-zero, then LuaTEX will not complain about non-expandable commands appearing in the middle of a \ifcsname expansion. Instead, it will keep getting expanded tokens from the input until it encounters an \endcsname command. Use with care! This command is experimental: if the input expansion is unbalanced wrt. \csname ...\endcsname pairs, the LuaTEX process may hang indefinately.

# 2.6.9 Font syntax

LuaTFX will accept a braced argument as a font name:

```
font\myfont = \{cmr10\}
```

This allows for embedded spaces, without the need for double quotes. Macro expansion takes place inside the argument.

# 2.7 Debugging

If \tracingonline is larger than 2, the node list display will also print the node number of the nodes.

# 3 LUA general

# 3.1 Initialization

#### 3.1.1 LUATEX as a LUA interpreter

There are some situations that make LuaTFX behave like a standalone Lua interpreter:

- if a --luaonly option is given on the commandline, or
- if the executable is named texlua (or luatexlua), or
- if the only non-option argument (file) on the commandline has the extension lua or luc.

In this mode, it will set Lua's arg[0] to the found script name, pushing preceding options in negative values and the rest of the commandline in the positive values, just like the Lua interpreter.

LuaTEX will exit immediately after executing the specified Lua script and is, in effect, a somewhat bulky standalone Lua interpreter with a bunch of extra preloaded libraries.

# 3.1.2 LUATEX as a LUA byte compiler

There are two situations that make LuaTEX behave like the Lua byte compiler:

- if a --luaconly option is given on the commandline, or
- if the executable is named texluac

In this mode, LuaTFX is exactly like luac from the standalone Lua distribution, except that it does not have the -1 switch, and that it accepts (but ignores) the --luaconly switch.

# 3.1.3 Other commandline processing

When the LuaTFX executable starts, it looks for the --lua commandline option. If there is no --lua option, the commandline is interpreted in a similar fashion as in traditional pdfTFX and Aleph. But if the option is present, LuaTFX will enter an alternative mode of commandline parsing in comparison to the standard web2c programs.

In this mode, a small series of actions is taken in order. At first, it will only interpret a small subset of the commandline directly:

--lua=s load and execute a Lua initialization script --safer disable easily exploitable Lua commands

--nosocket disable the Lua socket library

display help and exit --help --version display version and exit

Now it searches for the requested Lua initialization script. If it can not be found using the actual name given on the commandline, a second attempt is made by prepending the value of the environment variable LUATEXDIR, if that variable is defined.

Then it checks the **--safer** switch. You can use that to disable some Lua commands that can easily be abused by a malicious document. At the moment, this switch nils the following functions:

#### library functions

os execute exec setenv rename remove tmpdir

io popen output tmpfile

lfs rmdir mkdir chdir lock touch

And it makes io.open() fail on files that are opened for anything besides reading.

Next the initialization script is loaded and executed. From within the script, the entire commandline is available in the Lua table arg, beginning with arg [0], containing the name of the executable.

Commandline processing happens very early on. So early, in fact, that none of TEX's initializations have taken place yet. For that reason, the tables that deal with typesetting, like tex, token, node and pdf, are off-limits during the execution of the startup file (they are nilled). Special care is taken that texio.write and texio.write\_nl function properly, so that you can at least report your actions to the log file when (and if) it eventually becomes opened (note that TEX does not even know its \jobname yet at this point). See chapter 4 for more information about the LuaTEX-specific Lua extension tables.

The Lua initialization script is loaded into Lua state 0, and everything you do will remain visible during the rest of the run, with the exception of the aforementioned tex, token, node and pdf tables: those will be initialized to their documented state after the execution of the script. You should not store anything in variables or within tables with these four global names, as they will be overwritten completely.

We recommend you use the startup file only for your own TEX-independent initializations (if you need any), to parse the commandline, set values in the texconfig table, and register the callbacks you need. LuaTEX will fetch some of the other commandline options from the texconfig table at the end of script execution (see the description of the texconfig table later on in this document for more details on which ones exactly).

Unless the texconfig table tells LuaTEX not to initialize kpathsea at all (set texconfig.kpse\_init to false for that), LuaTEX acts on three more commandline options after the initialization script is finished:

#### flag meaning

--fmt=s set the format name

--progname=s set the progname (only for kpathsea)

--ini enable iniT<sub>F</sub>X mode

In order to initialize the built-in kpathsea library properly, LuaTEX needs to know the correct progname to use, and for that it needs to check --progname (and --ini and --fmt, if --progname is missing).

# 3.2 LUA changes

The C coroutine (coco) patches from luajit are applied to the Lua core, the used version is 1.1.3. See http://luajit.org/coco.html for details.

The read("\*line") function from the io library has been adjusted so that it is line-ending neutral: any of LF, CR or CR+LF are acceptable line endings.

The tostring() printer for numbers has been changed so that it returns 0 instead of something like 2e-5 (which confused TEX enormously) when the value is so small that TEX cannot distinguish it from zero.

Dynamic loading of .so and .dll files is disabled on all platforms.

luafilesystem has been extended with two extra boolean functions (isdir(filename) and isfile(filename)) and one extra string field in its attributes table (permissions).

The string library has an extra function: string.explode(s[,m]). This function returns an array containing the string argument s split into substrings based on the value of the string argument m. The second argument is a string that is either empty (this splits the string into characters), a single character (this splits on each occurrence of that character, possibly introducing empty strings), or a single character followed by the plus sign + (this special version does not create empty substrings). The default value for m is + (multiple spaces).

Note: m is not hidden by surrounding braces (as it would be if this function was written in TFX macros).

The **string** library also has six extra iterators that return strings piecemeal:

- string.utfvalues(s) (returns an integer value in the Unicode range)
- string.utfcharacters(s) (returns a string with a single utf-8 token in it)
- string.characters(s) (a string containing one byte)
- string.characterpairs(s) (two strings each containing one byte) will produce an empty second string in the string length was odd.
- string.bytes(s) (a single byte value)
- string.bytepairs(s) (two byte values) Will produce nil instead of a number as its second return value if the string length was odd.

The string.characterpairs() and string.bytepairs() are useful especially in the conversion of UTF-16 encoded data into UTF-8.

Note: The string library functions find etc. are not Unicode-aware. In cases where this is required (i. e. because the pattern used for searching contains characters above code point 127), the corresponding functions from unicode.utf8 should be used.

The os library has a few extra functions and variables:

os.exec(commandline) is a variation on os.execute.
 The commandline can be either a single string or a single table.

If the argument is a table: LuaTEX first checks if there is a value at integer index zero. If there is, this is the command to be executed. Otherwise, it will use the value at integer index one. (if neither are present, nothing at all happens).

The set of consecutive values starting at integer 1 in the table are the arguments that are passed on to the command (the value at index 1 becomes argv[0]). The command is searched for in the execution path, so there is normally no need to pass on a fully qualified pathname.

If the argument is a string, then it is automatically converted into a table by splitting on whitespace. In this case, it is impossible for the command and first argument to differ from each other.

In the string argument format, whitespace can be protected by putting (part of) an argument inside single or double quotes. One layer of quotes is interpreted by LuaTEX, and all occurrences of \", \' or \\ within the quoted text are un-escaped. In the table format, there is no string handling taking place.

This function normally does not return control back to the Lua script: the command will replace the current process. However, it will return the two values nil and 'error' if there was a problem while attempting to execute the command.

On windows, the current process is actually kept in memory until after the execution of the command has finished. This prevents crashes in situations where TEXLua scripts are run inside integrated TEX environments.

The original reason for this command is that it cleans out the current process before starting the new one, making it especially useful for use in TEXLua.

 os.spawn(commandline) is a returning version of os.exec, with otherwise identical calling conventions.

If the command ran ok, then the return value is the exit status of the command. Otherwise, it will return the two values nil and 'error'.

- os.setenv('key','value') This sets a variable in the environment. Passing nil instead of a value string will remove the variable.
- os.env This is a hash table containing a dump of the variables and values in the process environment at the start of the run. It is writeable, but the actual environment is *not* updated automatically.
- os.gettimeofday() Returns the current 'Unix time', but as a float. This function is not available on the SunOS platforms, so do not use this function for portable documents.
- os.times() Returns the current process times cf. the Unix C library 'times' call in seconds. This function is not available on the MS Windows and SunOS platforms, so do not use this function for portable documents.
- os.tmpdir() This will create a directory in the 'current directory' with the name luatex.XXXXXX where the X-es are replaced by a unique string. The function also returns this string, so you can lfs.chdir() into it, or nil if it failed to create the directory. The user is responsible for cleaning up at the end of the run, it does not happen automatically.
- os.type This is a string that gives a global indication of the class of operating system. The possible values are currently windows, unix, and msdos (you are unlikely to find this value 'in the wild').
- os.name This is a string that gives a more precise indication of the operating system. These possible
  values are not yet fixed, and for os.type values windows and msdos, the os.name values are
  simply windows and msdos

The list for the type unix is more precise: linux, freebsd, openbsd, solaris, sunos (pre-solaris), hpux, irix, macosx, bsd (unknown, but bsd-like), sysv (unknown, but sysv-like), generic (unknown).

(os.version is planned as a future extension)

In stock Lua, many things depend on the current locale. In LuaTEX, we can't do that, because it makes documents unportable. While LuaTEX is running if forces the following locale settings:

```
LC_CTYPE=C
LC_COLLATE=C
LC_NUMERIC=C
```

# 3.3 LUA modules

Some modules that are normally external to Lua are statically linked in with LuaTEX, because they offer useful functionality:

- slnunicode, from the Selene libraries, http://luaforge.net/projects/sln. (version 1.1)
  This library has been slightly extended so that the unicode.utf8.\* functions also accept the first 256 values of plane 18. This is the range LuaTFX uses for raw binary output, as explained above,
- luazip, from the kepler project, http://www.keplerproject.org/luazip/. (version 1.2.1, but patched for compilation with Lua 5.1)
- luafilesystem, also from the kepler project, http://www.keplerproject.org/luafilesystem/. (version 1.4.1)
- lpeg, by Roberto Ierusalimschy, http://www.inf.puc-rio.br/~roberto/lpeg.html. (version 0.8.1)

  Note: lpeg is not Unicode-aware, but interprets strings on a byte-per-byte basis. This mainly means that lpeg.S cannot be used with characters above code point 127, since those characters are encoded using two bytes, and thus lpeg.S will look for one of those two bytes when matching, not the combination of the two.
  - The same is true for lpeg.R, although the latter will display an error message if used with characters above code point 127: I.e.  $lpeg.R('a\ddot{a}')$  results in the message bad argument #1 to 'R' (range must have two characters), since to lpeg,  $\ddot{a}$  is two 'characters' (bytes), so  $a\ddot{a}$  totals three.
- Izlib, by Tiago Dionizio, http://mega.ist.utl.pt/~tngd/lua/. (version 0.2)
- md5, by Roberto Ierusalimschy http://www.inf.puc-rio.br/~roberto/md5/md5-5/md5.html.
- luasocket, by Diego Nehab http://www.tecgraf.puc-rio.br/~diego/professional/luasocket/ (version 2.0.2).

Note: the .lua support modules from luasocket are also preloaded inside the executable, there are no external file dependancies.

# 4 LUATEX LUA Libraries

The interfacing between TEX and Lua is facilitated by a set of library modules. The Lua libraries in this chapter are all defined and initialized by the LuaTEX executable. Together, they allow Lua scripts to query and change a number of TEX's internal variables, run various internal functions TEX, and set up LuaTEX's hooks to execute Lua code.

# 4.1 The tex library

The tex table contains a large list of virtual internal TEX parameters that are partially writable.

The designation 'virtual' means that these items are not properly defined in Lua, but are only frontends that are handled by a metatable that operates on the actual TEX values. As a result, most of the Lua table operators (like pairs and #) do not work on such items.

At the moment, it is possible to access almost every parameter that has these characteristics:

- You can use it after \the
- It is a single token.
- Some special others, see the list below

This excludes parameters that need extra arguments, like \the\scriptfont.

The subset comprising simple integer and dimension registers are writable as well as readable (stuff like \tracingcommands and \parindent).

# 4.1.1 Integer parameters

The integer parameters accept and return Lua numbers.

#### Read-write:

tex.adjdemerits	tex.errorcontextlines
tex.binoppenalty	tex.escapechar
tex.brokenpenalty	tex.exhyphenpenalty
tex.catcodetable	tex.fam
tex.clubpenalty	tex.finalhyphendemerits
tex.day	tex.floatingpenalty
tex.defaulthyphenchar	tex.globaldefs
tex.defaultskewchar	tex.hangafter
tex.delimiterfactor	tex.hbadness

#### Read-only:

tex.parshape tex.prevgraf tex.deadcycles tex.spacefactor

tex.insertpenalties

# 4.1.2 Dimension parameters

The dimension parameters accept Lua numbers (signifying scaled points) or strings (with included dimension). The result is always a number in scaled points.

#### Read-write:

tex.boxmaxdepth tex.delimitershortfall tex.displayindent tex.displaywidth tex.emergencystretch tex.hangindent tex.hfuzz tex.hoffset tex.hsize tex.lineskiplimit tex.mathsurround tex.maxdepth tex.nulldelimiterspace tex.overfullrule	tex.pagebottomoffset tex.pageheight tex.pageleftoffset tex.pagerightoffset tex.pagetopoffset tex.pagewidth tex.parindent tex.pdfdestmargin tex.pdfeachlinedepth tex.pdffirstlineheight tex.pdffirstlineheight tex.pdflastlinedepth tex.pdflastlinedepth	tex.pdfpageheight tex.pdfpagewidth tex.pdfpxdimen tex.pdfthreadmargin tex.pdfvorigin tex.predisplaysize tex.scriptspace tex.scriptspace tex.splitmaxdepth tex.vfuzz tex.voffset tex.vsize
Read-only:		
tex.pagedepth tex.pagefillstretch tex.pagefillstretch	tex.pagegoal tex.pageshrink tex.pagestretch	tex.prevdepth

# 4.1.3 Direction parameters

tex.pagefilstretch

The direction parameters are read-only and return a Lua string.

tex.bodydir tex.pagedir tex.textdir tex.mathdir tex.pardir

tex.pagetotal

# 4.1.4 Glue parameters

All glue parameters are read-only and return a userdata object that represents a glue\_spec node.

tex.abovedisplayshorttex.abovedisplayskip tex.belowdisplayshorttex.baselineskip skip skip

```
tex.belowdisplayskip tex.rightskip tex.xspaceskip
tex.leftskip tex.spaceskip
tex.lineskip tex.splittopskip
tex.parfillskip tex.tabskip
tex.parskip tex.topskip
```

# 4.1.5 Muglue parameters

All muglue parameters are read-only and return a Lua string.

```
tex.medmuskip tex.thinmuskip tex.thickmuskip
```

# 4.1.6 Tokenlist parameters

All tokenlist parameters are read-only and return a Lua string.

tex.errhelp	tex.everyjob	tex.pdfpageattr
tex.everycr	tex.everymath	tex.pdfpageresources
tex.everydisplay	tex.everypar	tex.pdfpagesattr
tex.everyeof	tex.everyvbox	tex.pdfpkmode
tex.everyhbox	tex.output	

#### 4.1.7 Convert commands

All 'convert' commands are read-only and return a Lua string. The supported commands at this moment are:

```
tex.pdftexrevision
tex.AlephVersion
tex.Alephrevision
                                        tex.fontname(number)
                                        tex.pdffontname(number)
tex.OmegaVersion
                                        tex.pdffontobjnum(number)
tex.Omegarevision
tex.eTeXVersion
                                        tex.pdffontsize(number)
tex.eTeXrevision
                                        tex.uniformdeviate(number)
tex.formatname
                                        tex.number(number)
tex.jobname
                                        tex.romannumeral(number)
tex.luatexrevision
                                        tex.pdfpageref(number)
                                        tex.pdfxformname(number)
tex.luatexdatestamp
tex.pdfnormaldeviate
                                        tex.fontidentifier(number)
tex.pdftexbanner
```

If you are wondering why this list looks haphazard; these are all the cases of the 'convert' internal command that do not require an argument, as well as the ones that require only a simple numeric value.

The special (lua-only) case of tex.fontidentifier returns the csname string that matches a font id number (if there is one).

#### 4.1.8 Last item commands

All 'last item' commands are read-only and return a number.

The supported commands at this moment are:

```
tex.lastpenalty
                           tex.pdflastannot
                                                      tex.eTeXversion
tex.lastkern
                           tex.pdflastxpos
                                                      tex.currentgrouplevel
tex.lastskip
                           tex.pdflastypos
                                                      tex.currentgrouptype
tex.lastnodetype
                           tex.pdfrandomseed
                                                      tex.currentiflevel
tex.inputlineno
                           tex.pdflastlink
                                                      tex.currentiftype
tex.badness
                           tex.luatexversion
                                                      tex.currentifbranch
                           tex.Alephversion
                                                      tex.pdflastximagecol-
tex.pdftexversion
tex.pdflastobi
                           tex.Omegaversion
                                                      ordepth
tex.pdflastxform
                           tex.Alephminorversion
tex.pdflastximage
                           tex.Omegaminorversion
                           tex.eTeXminorversion
tex.pdflastximagepages
```

### 4.1.9 Attribute, count, dimension, skip and token registers

TFX's attributes (\attribute), counters (\count), dimensions (\dimen), skips (\skip) and token (\toks) registers can be accessed and written to using five virtual sub-tables of the tex table:

```
tex.attribute
                            tex.dimen
                                                        tex.toks
tex.count
                            tex.skip
```

It is possible to use the names of relevant \attributedef, \countdef, \dimendef, \skipdef, or \toksdef control sequences as indices to these tables:

```
tex.count.scratchcounter = 0
enormous = tex.dimen['maxdimen']
```

In this case, LuaTFX looks up the value for you on the fly. You have to use a valid \countdef (or \attributedef, or \dimendef, or \skipdef, or \toksdef), anything else will generate an error (the intent is to eventually also allow <chardef tokens> and even macros that expand into a number).

The attribute and count registers accept and return Lua numbers.

The dimension registers accept Lua numbers (in scaled points) or strings (with an included absolute dimension; em and ex and px are forbidden). The result is always a number in scaled points.

The token registers accept and return Lua strings. Lua strings are converted to and from token lists using \the\toks style expansion: all category codes are either space (10) or other (12).

The skip registers accept and return <code>glue\_spec</code> userdata node objects (see the description of the node interface elsewhere in this manual).

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setdimen(<number> n, <string> s)
tex.setdimen(<string> s, <string> s)
tex.setdimen(<number> n, <number> n)
tex.setdimen(<string> s, <number> n)
<number> n = tex.getdimen(<number> n)
<number> n = tex.getdimen(<string> s)
tex.setcount(<number> n, <number> n)
tex.setcount(<string> s, <number> n)
<number> n = tex.getcount(<number> n)
<number> n = tex.getcount(<string> s)
tex.settoks (<number> n, <string> s)
tex.settoks (<string> s, <string> s)
<string> s = tex.gettoks (<number> n)
<string> s = tex.gettoks (<string> s)
tex.setskip (<number> n, <node> s)
tex.setskip (<string> s, <node> s)
<node> s = tex.getskip (<number> n)
<node> s = tex.getskip (<string> s)
```

# 4.1.10 Box registers

The current dimensions of \box registers can be read and altered using three other virtual sub-tables :

```
tex.wd
tex.ht
tex.dp
```

Boxes are indexed by number or by name. In macro packages **chardef** is normally used to refer to allocated box registers and LuaTEX is able to deal with these symbolic names.

The box size registers accept Lua numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setboxwd(<number> n, <number> n)
<number> n = tex.getboxwd(<number> n)

tex.setboxht(<number> n, <number> n)
<number> n = tex.getboxht(<number> n)

tex.setboxdp(<number> n, <number> n)
<number> n = tex.getboxdp(<number> n)
```

It is also possible to set and query actual boxes, using the node interface as defined in the node library:

```
tex.box
```

for array access, or

```
tex.setbox(<number> n, <node> s)
<node> n = tex.getbox(<number> n)
```

for function-based access.

Be warned that an assignment like

```
tex.box[0] = tex.box[2]
```

does not copy the node list, it just duplicates a node pointer. If \box2 will be cleared by TEX commands later on, the contents of \box0 becomes invalid as well. To prevent this from happening, always use node.copy\_list() unless you are assigning to a temporary variable:

```
tex.box[0] = node.copy_list(tex.box[2])
```

#### 4.1.11 Special list heads

The virtual table tex.lists contains the set of internal registers that keep track of building page lists.

description

circular list of pending insertions page\_ins\_head

contrib\_head the recent contributions

page\_head the page-so-far

hold\_head used for heldover items for next page adjust head head of the current \adjust list pre\_adjust\_head head of the current \adjust pre list

#### 4.1.12 Print functions

The tex table also contains the three print functions that are the major interface from Lua scripting to TEX.

The arguments to these three functions are all stored in an in-memory virtual file that is fed to the TFX scanner as the result of the expansion of \directlua.

The total amount of returnable text from a \directlua command is only limited by available system ram. However, each separate printed string has to fit completely in TFX's input buffer.

The result of using these functions from inside callbacks is undefined at the moment.

#### 4.1.12.1 tex.print

```
tex.print(<string> s, ...)
tex.print(<number> n, <string> s, ...)
```

Each string argument is treated by TEX as a separate input line.

The optional parameter can be used to print the strings using the catcode regime defined by \cat $codetable \ n.$  If n is not a valid catcode table, then it is ignored, and the currently active catcode regime is used instead.

The very last string of the very last tex.print() command in a \directlua will not have the \endlinechar appended, all others do.

#### 4.1.12.2 tex.sprint

```
tex.sprint(<string> s, ...)
tex.sprint(<number> n, <string> s, ...)
```

Each string argument is treated by TEX as a special kind of input line that makes it suitable for use as a partial line input mechanism:

- TEX does not switch to the 'new line' state, so that leading spaces are not ignored.
- No \endlinechar is inserted.
- Trailing spaces are not removed. (Note that this does not prevent TFX itself from eating spaces as result of interpreting the line. For example, in

```
before\directlua{tex.sprint("\\relax")tex.sprint(" inbetween")}after
```

the space before inbetween will be gobbled as a result of the 'normal' scanning of \relax).

#### 4.1.12.3 tex.write

```
tex.write(<string> s, ...)
```

Each string argument is treated by TEX as a special kind of input line that makes is suitable for use as a quick way to dump information:

- All catcodes on that line are either 'space' (for ' ') or 'character' (for all others).
- There is no \endlinechar appended.

# 4.1.13 Helper functions

#### 4.1.13.1 tex.round

```
<number> n = tex.round(<number> o)
```

Rounds Lua number o, and returns a number that is in the range of a valid TEX register value. If the number starts out of range, it generates a 'number to big' error as well.

#### 4.1.13.2 tex.scale

```
<number> n = tex.scale(<number> o, <number> delta)
 n = tex.scale(table o, <number> delta)
```

Multiplies the Lua numbers o and delta, and returns a rounded number that is in the range of a valid TEX register value. In the table version, it creates a copy of the table with all numeric top—level values scaled in that manner. If the multiplied number(s) are of range, it generates 'number to big' error(s) as well.

#### 4.1.13.3 tex.definefont

```
tex.definefont(<string> csname, <number> fontid)
tex.definefont(<boolean> global, <string> csname, <number> fontid)
```

Associates csname with the internal font number fontid. The definition is global if (and only if) global is specified and true (the setting of globaldefs is not taken into account).

#### 4.1.13.4 tex.primitives

```
 t = tex.primitives()
```

This function returns a hash table listing all primitives that LuaTEX knows about. The keys in the hash are primitives names, the values are tables representing tokens (see **section 4.2**). The third value is always zero.

#### 4.1.13.5 tex.extraprimitives

```
 t = tex.extraprimitives(<string> s, ...)
```

This function returns a list of the primitives that originate from the engine(s) given by the requested string value(s). The possible values and their (current) return values are:

#### name values

tex

Note that 'luatex' does not contain directlua, as that is considered to be a core primitive, along with all the TFX82 primitives, so it is part of the list that is returned from 'core.

Running tex.extraprimitives() will give you the complete list of primitives that are not defined at LuaTFX 0.40 -ini startup. It is exactly equivalent to tex.extraprimitives('etex', 'pdftex', 'omega', 'aleph', 'luatex')

#### 4.1.13.6 tex.enableprimitives

tex.enableprimitives(<string> prefix, primitive names)

This function accepts a prefix string and an array of primitive names.

For each combination of 'prefix' and 'name', the tex.enableprimitives first verifies that 'name' is and actual primitive (it must be returned by one of the tex.extraprimitives() calls explained above, or part of TFX82, or \directlua). If it is not, tex.enableprimitives does nothing and skips to the next pair.

But if it is, then it will contruct a csname variable by concatenating the 'prefix' and 'name', unless the 'prefix' is already the actual prefix of 'name'. In the latter case, it will discard the 'prefix', and just use 'name'.

Then it will check for the existence of the constructed csname. If the csname is currently undefined (note: that is not the same as \relax), it will globally define the csname to have the meaning: run code

belonging to the primitive 'name'. If for some reason the csname is already defined, it does nothing and tries the next pair.

An example:

```
tex.enableprimitives('LuaTeX', {'formatname'})
```

will define \LuaTeXformatname with the same intrinsic meaning as the documented primitive \formatname, provided that the control sequences \LuaTeXformatname is currently undefined.

Second example:

```
tex.enableprimitives('Omega',tex.primitives ('omega'))
```

will define a whole series of csnames like \Omegatextdir, \Omegapardir, etc., but it will stick with \OmegaVersion instead of creating the doubly-prefixed \OmegaOmegaVersion.

Starting with version 0.40 (and this is why the above two functions are needed), Lua $T_FX$  in --ini mode will contain only the TEX82 primitives and \directlua, no extra primitives at all.

So, if you want to have all the new functionality available using their default names, as it is now, you will have to add

```
\expandafter\ifx\csname directlua\endcsname \relax \else
   \directlua {tex.enableprimitives('',tex.primitives ())}
\fi
```

near the beginning of your format generation file. Or you can choose different prefixes for different subsets, as you see fit.

Calling some form of tex.enableprimitives() is highly important though, because if you do not, you will end up with a TFX82-lookalike that can run lua code but not do much else. The defined csnames are (of course) saved in the format and will be available runtime.

# The token library

The token table contains interface functions to TFX's handling of tokens. These functions are most useful when combined with the token\_filter callback, but they could be used standalone as well.

A token is represented in Lua as a small table. For the moment, this table consists of three numeric entries:

index	meaning	description
1	command code	this is a value between 0 and 130 (approximately)
2	command modifier	this is a value between 0 and 2 <sup>21</sup>
3	control sequence id	for commands that are not the result of control sequences, like letters and
		characters, it is zero, otherwise, it is a number pointing into the 'equivalence
		table'

## 4.2.1 token.get\_next

```
token t = token.get_next()
```

This fetches the next input token from the current input source, without expansion.

## 4.2.2 token.is\_expandable

```
<boolean> b = token.is expandable(token t)
```

This tests if the token t could be expanded.

## 4.2.3 token.expand

```
token.expand()
```

If a token is expandable, this will expand one level of it, so that the first token of the expansion will now be the next token to be read by token.get next().

## 4.2.4 token.is activechar

```
<boolean> b = token.is activechar(token t)
```

This is a special test that is sometimes handy. Discovering whether some control sequence is the result of an active character turned out to be very hard otherwise.

#### 4.2.5 token.create

```
token t = token.create(<string> csname)
token t = token.create(<number> charcode)
token t = token.create(<number> charcode, <number> catcode)
```

This is the token factory. If you feed it a string, then it is the name of a control sequence (without leading backslash), and it will be looked up in the equivalence table.

If you feed it number, then this is assumed to be an input character, and an optional second number gives its category code. This means it is possible to overrule a character's category code, with a few exceptions: the category codes 0 (escape), 9 (ignored), 13 (active), 14 (comment), and 15 (invalid) cannot occur inside a token. The values 0, 9, 14 and 15 are therefore illegal as input to token.create(), and active characters will be resolved immediately.

Note: unknown string sequences and never defined active characters will result in a token representing an 'undefined control sequence' with a near-random name. It is *not* possible to define brand new control sequences using token.create!

## 4.2.6 token.command name

```
<string> commandname = token.command_name(<token> t)
```

This returns the name associated with the 'command' value of the token in LuaTFX. There is not always a direct connection between these names and primitives. For instance, all \ifxxx tests are grouped under if\_fest, and the 'command modifier' defines which test is to be run.

## 4.2.7 token.command id

```
<number> i = token.command id(<string> commandname)
```

This returns a number that is the inverse operation of the previous command, to be used as the first item in a token table.

## 4.2.8 token.csname\_name

```
<string> csname = token.csname_name(<token> t)
```

This returns the name associated with the 'equivalence table' value of the token in LuaTFX. It returns the string value of the command used to create the current token, or an empty string if there is no associated control sequence.

Keep in mind that there are potentially two control sequences that return the same csname string: single character control sequences and active characters have the same 'name'.

## 4.2.9 token.csname id

```
<number> i = token.csname_id(<string> csname)
```

This returns a number that is the inverse operation of the previous command, to be used as the third item in a token table.

# 4.3 The node library

The node library contains functions that facilitate dealing with (lists of) nodes and their values. They allow you to create, alter, copy, delete, and insert LuaTFX node objects, the core objects within the typesetter.

LuaTFX nodes are represented in Lua as userdata with the metadata type luatex.node. The various parts within a node can be accessed using named fields.

Each node has at least the three fields next, id, and subtype:

- The next field returns the userdata object for the next node in a linked list of nodes, or nil, if there is no next node.
- The id indicates TEX's 'node type'. The field id has a numeric value for efficiency reasons, but some of the library functions also accept a string value instead of id.
- The subtype is another number. It often gives further information about a node of a particular id, but it is most important when dealing with 'whatsits', because they are differentiated solely based on their subtype.

The other available fields depend on the id (and for 'whatsits', the subtype) of the node. Further details on the various fields and their meanings are given in **chapter 8**.

Support for unset (alignment) nodes is partial: they can be queried and modified from Lua code, but not created.

Nodes can be compared to each other, but: you are actually comparing indices into the node memory. This means that equality tests can only be trusted under very limited conditions. It will not work correctly in any situation where one of the two nodes has been freed and/or reallocated: in that case, there will be false positives.

At the moment, memory management of nodes should still be done explicitly by the user. Nodes are not 'seen' by the Lua garbage collector, so you have to call the node freeing functions yourself when you are no longer in need of a node (list). Nodes form linked lists without reference counting, so you have to be careful that when control returns back to LuaTEX itself, you have not deleted nodes that are still referenced from a next pointer elsewhere, and that you did not create nodes that are referenced more than once.

There are statistics available with regards to the allocated node memory, which can be handy for tracing.

## 4.3.1 Node handling functions

## **4.3.1.1** node.types

```
table t = node.types()
```

This function returns an array that maps node id numbers to node type strings, providing an overview of the possible top-level id types.

#### 4.3.1.2 node.whatsits

```
table t = node.whatsits()
```

TEX's 'whatsits' all have the same id. The various subtypes are defined by their subtype. The function is much like node.types, except that it provides an array of subtype mappings.

#### 4.3.1.3 node.id

```
<number> id = node.id(<string> type)
```

This converts a single type name to its internal numeric representation.

## 4.3.1.4 node.subtype

```
<number> subtype = node.subtype(<string> type)
```

This converts a single whatsit name to its internal numeric representation (subtype).

## 4.3.1.5 node.type

```
<string> type = node.type(<number> id)
```

This converts a internal numeric representation to an external string representation.

#### **4.3.1.6** node.fields

```
table t = node.fields(<number> id)
table t = node.fields(<number> id, <number> subtype)
```

This function returns an array of valid field names for a particular type of node. If you want to get the valid fields for a 'whatsit', you have to supply the second argument also. In other cases, any given second argument will be silently ignored.

This function accepts string id and subtype values as well.

## 4.3.1.7 node.has\_field

```
<boolean> t = node.has_field(<node> n, <string> field)
```

This function returns a boolean that is only true if n is actually a node, and it has the field.

#### 4.3.1.8 node.new

```
<node> n = node.new(<number> id)
<node> n = node.new(<number> id, <number> subtype)
```

Creates a new node. All of the new node's fields are initialized to either zero or nil except for id and subtype (if supplied). If you want to create a new whatsit, then the second argument is required, otherwise it need not be present. As with all node functions, this function creates a node on the TEX level.

This function accepts string id and subtype values as well.

### 4.3.1.9 node.free

```
node.free(<node> n)
```

Removes the node n from TFX's memory. Be careful: no checks are done on whether this node is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

## 4.3.1.10 node.flush list

```
node.flush_list(<node> n)
```

Removes the node list n and the complete node list following n from  $T_EX$ 's memory. Be careful: no checks are done on whether any of these nodes is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

## **4.3.1.11** node.copy

```
<node> m = node.copy(<node> n)
```

Creates a deep copy of node n, including all nested lists as in the case of a hlist or vlist node. Only the next field is not copied.

## 4.3.1.12 node.copy\_list

```
<node> m = node.copy_list(<node> n)
```

Creates a deep copy of the node list that starts at n.

#### 4.3.1.13 node.hpack

```
<node> h = node.hpack(<node> n)
<node> h = node.hpack(<node> n, <number> w, <string> info)
```

This function creates a new hlist by packaging the list that begins at node n into a horizontal box. With only a single argument, this box is created using the natural width of its components. In the three argument form, info must be either additional or exactly, and w is the additional (\hbox spread) or exact (\hbox to) width to be used.

Caveat: at this moment, there can be unexpected side-effects to this function, like updating some of the \marks and \inserts. Also note that the content of h is the original node list n: if you call

node.free(h) you will also free the node list itself, unless you explicitly set the list field to nil beforehand. And in a similar way, calling node.free(n) will invalidate h as well!

## 4.3.1.14 node.mlist\_to\_hlist

```
<node> h = node.mlist_to_hlist(<node> n,
             <string> displaytype, <boolean> penalties)
```

This runs the internal mlist to hlist conversion, converting the math list in  $\mathbf{n}$  into the horizontal list  $\mathbf{h}$ . The interface is exactly the same as for the callback mlist\_to\_hlist.)

#### 4.3.1.15 node.slide

```
<node> m = node.slide(<node> n)
```

Returns the last node of the node list that starts at n. As a side-effect, it also creates a reverse chain of prev pointers between nodes.

## 4.3.1.16 node.length

```
<number> i = node.length(<node> n)
<number> i = node.length(<node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at  ${\tt n}$ . If  ${\tt m}$  is also supplied it stops at m instead of at the end of the list. The node m is not counted.

#### 4.3.1.17 node.count

```
<number> i = node.count(<number> id, <node> n)
<number> i = node.count(<number> id, <node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at n that have an matching id field. If m is also supplied, counting stops at m instead of at the end of the list. The node m is not counted.

This function also accept string id's.

#### 4.3.1.18 node.traverse

```
<node> t = node.traverse(<node> n)
```

This is an iterator that loops over the node list that starts at n.

## 4.3.1.19 node.traverse\_id

```
<node> t = node.traverse_id(<number> id, <node> n)
```

This is an iterator that loops over all the nodes in the list that starts at n that have a matching id field.

#### 4.3.1.20 node.remove

```
<node> head, current = node.remove(<node> head, <node> current)
```

This function removes the node current from the list following head. It is your responsibility to make sure it is really part of that list. The return values are the new head and current nodes. The returned current is the node in the calling argument, and is only passed back as a convenience (its next field will be cleared). The returned head is more important, because if the function is called with current equal to head, it will be changed.

## 4.3.1.21 node.insert\_before

```
<node> head, new = node.insert_before(<node> head, <node> current, <node>
new)
```

This function inserts the node new before current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the (potentially mutated) head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

### 4.3.1.22 node.insert\_after

```
<node> head, new = node.insert_after(<node> head, <node> current, <node>
new)
```

This function inserts the node new after current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

## 4.3.1.23 node.first\_character

```
<node> n = node.first_character(<node> n)
<node> n = node.first_character(<node> n, <node> m)
```

Returns the first node that is a glyph node with a subtype indicating it is a character, or nil.

## 4.3.1.24 node.ligaturing

```
<node> h, <node> t, <boolean> success = node.ligaturing(<node> n)
<node> h, <node> t, <boolean> success = node.ligaturing(<node> n, <node> m)
```

Apply  $T_EX$ -style ligaturing to the specified nodelist. The tail node m is optional. The two returned nodes h and t are the new head and tail (both n and m can change into a new ligature).

## 4.3.1.25 node.kerning

```
<node> h, <node> t, <boolean> success = node.kerning(<node> n)
<node> h, <node> t, <boolean> success = node.kerning(<node> n, <node> m)
```

Apply TEX-style kerning to the specified nodelist. The tail node m is optional. The two returned nodes h and t are the head and tail (either one of these can be an inserted kern node, because special kernings with word boundaries are possible).

## 4.3.1.26 node.unprotect\_glyphs

```
node.unprotect_glyphs(<node> n)
```

Substracts 256 from all glyph node subtypes. This and the next function are helpers to convert from characters to glyphs during node processing.

## 4.3.1.27 node.protect\_glyphs

```
node.protect_glyphs(<node> n)
```

Adds 256 to all glyph node subtypes in the node list starting at n, except that if the value is 1, it adds only 255. The special handling of 1 means that characters will become glyphs after substraction of 256.

### 4.3.1.28 node.last\_node

```
<node> n = node.last_node()
```

This function pops the last node from  $T_EX's$  'current list'. It returns that node, or  $\mathtt{nil}$  if the current list is empty.

#### 4.3.1.29 node.write

```
node.write(<node> n)
```

This is an experimental function that will append a node list to TEX's 'current list'. There is no error checking yet!

## 4.3.2 Attribute handling

Attributes appear as linked list of userdata objects in the attr field of individual nodes. They can be handled individually, but it is much safer and more efficient to use the dedicated functions associated with them.

## 4.3.2.1 node.has\_attribute

```
<number> v = node.has_attribute(<node> n, <number> id)
<number> v = node.has attribute(<node> n, <number> id, <number> val)
```

Tests if a node has the attribute with number id set. If val is also supplied, also tests if the value matches val. It returns the value, or, if no match is found, nil.

## 4.3.2.2 node.set\_attribute

```
node.set_attribute(<node> n, <number> id, <number> val)
```

Sets the attribute with number id to the value val. Duplicate assignments are ignored. [needs explanation]

#### 4.3.2.3 node.unset\_attribute

```
<number> v = node.unset_attribute(<node> n, <number> id, <number> val)
<number> v = node.unset_attribute(<node> n, <number> id)
```

Unsets the attribute with number id. If val is also supplied, it will only perform this operation if the value matches val. Missing attributes or attribute-value pairs are ignored.

If the attribute was actually deleted, returns its old value. Otherwise, returns nil.

## 4.4 The texio library

This library takes care of the low-level I/O interface.

## 4.4.1 Printing functions

#### **4.4.1.1** texio.write

```
texio.write(<string> target, <string> s, ...)
texio.write(<string> s, ...)
```

Without the target argument, writes all given strings to the same location(s) TFX writes messages to at this moment. If \batchmode is in effect, it writes only to the log, otherwise it writes to the log and the terminal.

The optional target can be one of three possibilities: term, log or term and log.

Note: If several strings are given, and if the first of these strings is or might be one of the targets above, the target must be specified explicitly to prevent Lua from interpreting the first string as the target.

## 4.4.1.2 texio.write\_nl

```
texio.write_nl(<string> target, <string> s, ...)
texio.write_nl(<string> s, ...)
```

This function behaves like texio.write, but make sure that the given strings will appear at the beginning of a new line. You can pass a single empty string if you only want to move to the next line.

#### The pdf library 4.5

This table contains the current h and v values that define the location on the output page. The values can be queried and set using scaled points as units.

```
pdf.v
pdf.h
```

The associated function calls are

```
pdf.setv(<number> n)
<number> n = pdf.getv()
pdf.seth(<number> n)
<number> n = pdf.geth()
```

It also holds a print function to write stuff to the pdf document that can be used from within a \latelua argument. This function is not to be used inside \directlua unless you know exactly what you are doing.

```
pdf.print
pdf.print(<string> s)
pdf.print(<string> type, <string> s)
```

The optional parameter can be used to mimic the behavior of \pdfliteral: the type is direct or page.

# 4.6 The img library

The img library can be used as an alternative to \pdfximage and \pdfrefximage, and the associated 'satellite' commands like \pdfximagebbox. Image objects can also be used within virtual fonts via the image command listed in section 7.2.

```
img.new
<image> var = img.new()
<image> var = img.new(image_spec)
```

This function creates a userdata object of type 'image'. The image\_spec argument is optional. If it is given, it must be a table, and that table must contain a filename key. A number of other keys can also be useful, these are explained below.

You can either say

```
a=img.new()
followed by
a.filename="foo.png"
```

or you can put the file name (and some or all of the other keys) into a table directly, like so:

```
a=img.new{filename='foo.pdf',page=1}
```

The generated <image> userdata object allows access to a set of user-specified values as well as a set of values that are normally filled in and updated automatically by LuaTEX itself. Some of those are derived from the actual image file, others are updated to reflect the pdf output status of the object.

There is one required user-specified field: the file name (filename). It can optionally be augmented by the requested image dimensions (width, depth, height), user-specified image attributes (attr), the requested pdf page identifier (page), the requested boundingbox (pagebox) for pdf inclusion, the requested color space object (colorspace).

The function img.new does not access the actual image file, it just creates the <image> userdata object and initializes some memory structures. The <image> object and its internal structures are automatically garbage collected.

Once the image is scanned, all the values in the <image> become frozen, and you cannot change them any more.

## img.keys

```
 keys = img.keys()
```

This function returns a list of all the possible image\_spec keys, both user-supplied and automatic ones.

field name	type	description
depth	number	the image depth for LuaTEX (in scaled points)
height	number	the image height for LuaT <sub>E</sub> X (in scaled points)
width	number	the image width for LuaTEX (in scaled points)
transform	number	the image transform, integer number 07
attr	string	the image attributes for LuaTEX
filename	string	the image file name
stream	string	the raw stream data for an /Xobject /Form object
page	??	the identifier for the requested image page (type is number or string, default is
		the number 1)
pagebox	string	the requested bounding box, one of none, media, crop, bleed, trim, art
bbox	table	table with 4 boundingbox dimensions 11x, 11y, urx, and ury overruling the
		pagebox entry
filepath	string	the full (expanded) file name of the image
colordepth	number	the number of bits used by the color space
colorspace	number	the color space object number
imagetype	string	one of pdf, png, jpg, jbig2, or nil
objnum	number	the pdf image object number
index	number	the pdf image name suffix
pages	number	the total number of available pages
xsize	number	the natural image width
ysize	number	the natural image height
xres	number	the horizontal natural image resolution (in dpi)
yres	number	the vertical natural image resolution (in dpi)

A running (undefined) dimension in width, height, or depth is represented as nil in Lua, so if you want to load an image at its 'natural' size, you do not have to specify any of those three fields.

The stream parameter allows to fabricate an /XObject /Form object from a string giving the stream contents, e.g., for a filled rectangle:

```
a.stream = "0 0 20 10 re f"
```

When writing the image, an /Xobject /Form object is created, like with embedded pdf file writing. The object is written out only once. The stream key requires that also the bbox table is given. The stream key conflicts with the filename key. The transform key works as usual also with stream.

The bbox key needs a table with four boundingbox values, e.g.:

```
a.bbox = {"30bp", 0, "225bp", "200bp"}
```

This replaces and overrules any given pagebox value; with given bbox the box dimensions coming with an embedded pdf file are ignored. The xsize and ysize dimensions are set accordingly, when the image is scaled. The bbox parameter is ignored for non-pdf images.

The transform allows to mirror and rotate the image in steps of 90 deg. The default value 0 gives an unmirrored, unrotated image. Values 1-3 give counterclockwise rotation by 90, 180, or 270 degrees, whereas with values 4-7 the image is first mirrored and then rotated counterclockwise by 90, 180, or 270 degrees. The transform operation gives the same visual result as if you would externally preprocess the image by a graphics tool and then use it by LuaTFX. If a pdf file to be embedded already contains a /Rotate specification, the rotation result is the combination of the /Rotate rotation followed by the transform operation.

#### img.scan

```
<image> var = img.scan(<image> var)
<image> var = img.scan(image_spec)
```

When you say img.scan(a) for a new image, the file is scanned, and variables such as xsize, ysize, image type, number of pages, and the resolution are extracted. Each of the width, height, depth fields are set up according to the image dimensions, if they were not given an explicit value already. An image file will never be scanned more than once for a given image variable. With all subsequent img.scan(a) calls only the dimensions are again set up (if they have been changed by the user in the meantime).

For ease of use, you can do right-away a

```
<image> a = img.scan { filename = "foo.png" }
```

without a prior img.new.

Nothing is written yet at this point, so you can do a=img.scan, retrieve the available info like image width and height, and then throw away a again by saying a=nil. In that case no image object will be reserved in the PDF, and the used memory will be cleaned up automatically.

```
img.copy
```

```
<image> var = img.copy(<image> var)
<image> var = img.copy(image_spec)
```

If you say a = b, then both variables point to the same <image> object. if you want to write out an image with different sizes, you can do a b=img.copy(a).

Afterwards, a and b still reference the same actual image dictionary, but the dimensions for b can now be changed from their initial values that were just copies from a.

### img.write

```
<image> var = img.write(<image> var)
<image> var = img.write(image_spec)
```

By img.write(a) a pdf object number is allocated, and a whatsit node of subtype pdf\_refximage is generated and put into the output list. By this the image a is placed into the page stream, and the image file is written out into an image stream object after the shipping of the current page is finished.

Again you can do a terse call like

```
img.write { filename = "foo.png" }
```

The <image> variable is returned in case you want it for later processing.

### img.immediatewrite

```
<image> var = img.immediatewrite(<image> var)
<image> var = img.immediatewrite(image_spec)
```

By img.immediatewrite(a) a pdf object number is allocated, and the image file for image a is written out immediately into the pdf file as an image stream object (like with \immediate\pdfximage). The object number of the image stream dictionary is then available by the objnum key. No pdf\_refximage whatsit node is generated. You will need a img.write(a) or img.node(a) call to let the image appear on the page, or reference it by another trick; else you will have a dangling image object in the pdf file.

Also here you can do a terse call like

```
a = img.immediatewrite { filename = "foo.png" }
```

The <image> variable is returned and you will most likely need it.

#### img.node

```
<node> n = img.node(<image> var)
<node> n = img.node(image_spec)
```

This function allocates a pdf object number and returns a whatsit node of subtype pdf\_refximage, filled with the image parameters width, height, depth, and objnum. Also here you can do a terse call like:

```
n = img.node { filename = "foo.png" }
```

This example outputs an image:

```
node.write(img.node{filename="foo.png"})
```

```
img.types
```

```
 types = img.types()
```

This function returns a list with the supported image file type names, currently these are pdf, png, jpg, and jbig2.

## img.boxes

```
 boxes = img.boxes()
```

This function returns a list with the supported pdf page box names, currently these are media, crop, bleed, trim, and art (all in lowercase letters).

# The mplib library

The MetaPost library interface registers itself in the table mplib. It is based on MPlib version 1.102.

#### mplib.new 4.7.1

To create a new MetaPost instance, call

```
<mpinstance> mp = mplib.new({...})
```

This creates the mp instance object. The argument hash can have a number of different fields, as follows:

name	type	description	detault
error_line	number	error line width	79
<pre>print_line</pre>	number	line length in ps output	100
main_memory	number	total memory size	5000
hash_size	number	hash size	16384
param_size	number	max. active macro parameters	150
max_in_open	number	max. input file nestings	10
$random\_seed$	number	the initial random seed	variable
interaction	string	the interaction mode, one of batch,	errorstop
		nonstop, scroll, errorstop	
ini_version	boolean	the —ini switch	true
mem_name	string	mem	plain

```
job_name string --jobname mpout
find_file function a function to find files only local files

The find_file function should be of this form:

<string> found = finder (<string> name, <string> mode, <string> type)

with:

name the requested file

mode the file mode: r or w

type the kind of file, one of: mp, mem, tfm, map, pfb, enc
```

Return either the full pathname of the found file, or nil if the file cannot be found.

## 4.7.2 mp:statistics

You can request statistics with:

```
 stats = mp:statistics()
```

This function returns the vital statistics for an MPlib instance. There are four fields, giving the maximum number of used items in each of the four statically allocated object classes:

```
main_memory number memory size
hash_size number hash size
param_size number simultaneous macro parameters
max_in_open number input file nesting levels
```

## 4.7.3 mp:execute

You can ask the MetaPost interpreter to run a chunk of code by calling

```
local rettable = mp:execute('metapost language chunk')
```

for various bits of MetaPost language input. Be sure to check the rettable.status (see below) because when a fatal MetaPost error occurs the MPlib instance will become unusable thereafter.

Generally speaking, it is best to keep your chunks small, but beware that all chunks have to obey proper syntax, like each of them is a small file. For instance, you cannot split a single statement over multiple chunks.

In contrast with the normal standalone mpost command, there is *no* implied 'input' at the start of the first chunk.

## **4.7.4** mp:finish

```
local rettable = mp:finish()
```

If for some reason you want to stop using an MPlib instance while processing is not yet actually done, you can call mp:finish. Eventually, used memory will be freed and open files will be closed by the Lua garbage collector, but an explicit mp:finish is the only way to capture the final part of the output streams.

#### 4.7.5 Result table

The return value of mp: execute and mp:finish is a table with a few possible keys (only status is always quaranteed to be present).

```
output to the 'log' stream
loq
        string
                  output to the 'term' stream
term
        string
        string
                  output to the 'error' stream (only used for 'out of memory')
error
status
        number
                  the return value: 0=qood, 1=warning, 2=errors, 3=fatal error
                  an array of generated figures (if any)
fiq
        table
```

When status equals 3, you should stop using this MPlib instance immediately, it is no longer capable of processing input.

If it is present, each of the entries in the fig array is a userdata representing a figure object, and each of those has a number of object methods you can call:

```
boundingbox
              function returns the bounding box, as an array of 4 values
postscript
              function
                        return a string that is the ps output of the fig
objects
              function
                        returns the actual array of graphic objects in this fig
              function
                        returns a deep copy of the array of graphic objects in this fig
copy_objects
filename
              function
                        the filename this fig's PostScript output would have written to in standalone
                        mode
                        the charwd value
width
              function
height
              function
                        the charht value
depth
              function
                        the chardp value
italcorr
              function the charit value
charcode
              function the (rounded) charcode value
```

NOTE: you can call fig:objects() only once for any one fig object!

When the boundingbox represents a 'negated rectangle', i.e. when the first set of coordinates is larger than the second set, the picture is empty.

Graphical objects come in various types that each have a different list of accessible values. The types are: fill, outline, text, start\_clip, stop\_clip, start\_bounds, stop\_bounds, special.

There is helper function (mplib.fields(obj)) to get the list of accessible values for a particular object, but you can just as easily use the tables given below).

All graphical objects have a field type that gives the object type as a string value, that not explicit mentioned in the tables. In the following, numbers are PostScript points represented as a floating point number, unless stated otherwise. Field values that are of table are explained in the next section.

#### 4.7.5.1 fill

```
table
                      the list of knots
path
            table
                      the list of knots for the reversed trajectory
htap
pen
            table
                      knots of the pen
color
            table
                      the object's color
linejoin
            number
                      line join style (bare number)
miterlimit
            number
                      miterlimit
prescript
            string
                      the prescript text
postscript
            string
                      the postscript text
```

The entries htap and pen are optional.

There is helper function (mplib.pen\_info(obj)) that returns a table containing a bunch of vital characteristics of the used pen (all values are floats):

```
width number width of the pen rx number x scale sx number xy multiplier sy number yx multiplier ry number y scale tx number x offset ty number y offset
```

#### 4.7.5.2 outline

```
the list of knots
            table
path
                      knots of the pen
            table
pen
color
            table
                      the object's color
linejoin
            number
                      line join style (bare number)
miterlimit
            number
                      miterlimit
linecap
            number
                      line cap style (bare number)
            table
                      representation of a dash list
dash
            string
                      the prescript text
prescript
postscript
            string
                      the postscript text
```

The entry dash is optional.

#### 4.7.5.3 text

```
text
            string
                     the text
font
                     font tfm name
            string
dsize
            number
                     font size
color
            table
                     the object's color
width
            number
height
            number
            number
depth
transform
            table
                      a text transformation
                     the prescript text
prescript
            string
postscript
           string
                     the postscript text
```

## 4.7.5.4 special

prescript string special text

## 4.7.5.5 start\_bounds, start\_clip

path table the list of knots

## 4.7.5.6 stop\_bounds, stop\_clip

Here are no fields available.

## 4.7.6 Subsidiary table formats

## 4.7.6.1 Paths and pens

Paths and pens (that are really just a special type of paths as far as MPlib is concerned) are represented by an array where each entry is a table that represents a knot.

left_type	string	when present: 'endpoint', but ususally absent
right_type	string	like left_type
x_coord	number	X coordinate of this knot
y_coord	number	Y coordinate of this knot
left_x	number	X coordinate of the precontrol point of this knot
left_y	number	Y coordinate of the precontrol point of this knot
right_x	number	X coordinate of the postcontrol point of this knot
right_y	number	Y coordinate of the postcontrol point of this knot

There is one special case: pens that are (possibly transformed) ellipses have an extra string-valued key type with value elliptical besides the array part containing the knot list.

#### 4.7.6.2 Colors

A color is an integer array with 0, 1, 3 or 4 values:

```
marking only
                  no values
1
   greyscale
                   one value in the range (0,1), 'black' is 0
3 rqb
                   three values in the range (0,1), 'black' is 0,0,0
                   four values in the range (0,1), 'black' is 0,0,0,1
4 cmuk
```

If the color model of the internal object was unitialized, then it was initialized to the values representing 'black' in the colorspace defaultcolormodel that was in effect at the time of the shipout.

#### 4.7.6.3 Transforms

Each transform is a six-item array.

```
1 number represents x
2 number represents y
3 number represents xx
4 number represents yx
5 number represents xy
6 number represents yy
```

Note that the translation (index 1 and 2) comes first. This differs from the ordering in PostScript, where the translation comes last.

#### 4.7.6.4 Dashes

Each dash is two-item hash, using the same model as PostScript for the representation of the dashlist. dashes is an array of 'on' and 'off', values, and offset is the phase of the pattern.

```
dashes
                  an array of on-off numbers
        hash
offset
        number the starting offset value
```

#### 4.7.7 Character size information

These functions find the size of a gluph in a defined font. The fontname is the same name as the argument to infont; the char is a glyph id in the range 0 to 255; the returned w is in AFM units.

```
4.7.7.1 mp.char_width
<number> w = mp.char_width(<string> fontname, <number> char)
4.7.7.2 mp.char_height
<number> w = mp.char_height(<string> fontname, <number> char)
4.7.7.3 mp.char_depth
<number> w = mp.char_depth(<string> fontname, <number> char)
```

# 4.8 The callback library

This library has functions that register, find and list callbacks.

The callback library is only available in Lua state zero (0).

```
id, error = callback.register(<string> callback_name,function callback_func)
id, error = callback.register(<string> callback_name,nil)
```

where the callback\_name is a predefined callback name, see below. The function returns the internal id of the callback or nil, if the callback could not be registered. In the latter case, error contains an error message, otherwise it is nil.

LuaTEX internalizes the callback function in such a way that it does not matter if you redefine a function accidentally.

Callback assignments are always global. You can use the special value nil instead of a function for clearing the callback.

Currently, callbacks are not dumped into the format file.

```
table info = callback.list()
```

The keys in the table are the known callback names, the value is a boolean where true means that the callback is currently set (active).

```
function f = callback.find(callback_name)
```

If the callback is not set, callback.find returns nil.

## 4.8.1 File discovery callbacks

## 4.8.1.1 find\_read\_file and find\_write\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (number id_number, <string> asked_name)
```

Arguments:

id\_number

asked\_name

This is the user-supplied filename, as found by \input, \openin or \openout.

Return value:

actual\_name

This is the filename used. For the very first file that is read in by TEX, you have to make sure you return an actual\_name that has an extension and that is suitable for use as jobname. If you don't, you will have to manually fix the name of the log file and output file after LuaTEX is finished, and an eventual format filename will become mangled. That is because these file names depend on the jobname.

You have to return nil if the file cannot be found.

### 4.8.1.2 find\_font\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (<string> asked_name)
```

The asked\_name is an off or tfm font metrics file.

Return nil if the file cannot be found.

### 4.8.1.3 find\_output\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (<string> asked_name)
```

The asked\_name is the pdf or dvi file for writing.

## 4.8.1.4 find\_format\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (<string> asked_name)
```

The asked\_name is a format file for reading (the format file for writing is always opened in the current directory).

## 4.8.1.5 find\_vf\_file

Like find\_font\_file, but for virtual fonts. This applies to both Aleph's ovf files and traditional Knuthian vf files.

## 4.8.1.6 find\_ocp\_file

Like find\_font\_file, but for ocp files.

#### 4.8.1.7 find\_map\_file

Like find\_font\_file, but for map files.

### 4.8.1.8 find\_enc\_file

Like find\_font\_file, but for enc files.

### 4.8.1.9 find\_sfd\_file

Like find\_font\_file, but for subfont definition files.

### **4.8.1.10** find\_pk\_file

Like find\_font\_file, but for pk bitmap files. The argument name is a bit special in this case. Its form is

```
<base res>dpi/<fontname>.<actual res>pk
```

So you may be asked for 600dpi/manfnt.720pk. It is up to you to find a 'reasonable' bitmap file to go with that specification.

## 4.8.1.11 find\_data\_file

Like find\_font\_file, but for embedded files (\pdfobj file '...').

## 4.8.1.12 find\_opentype\_file

Like find\_font\_file, but for OpenType font files.

## 4.8.1.13 find\_truetype\_file and find\_type1\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (<string> asked_name)
```

The asked\_name is a font file. This callback is called while LuaTEX is building its internal list of needed font files, so the actual timing may surprise you. Your return value is later fed back into the matching read\_file callback.

Strangely enough, find\_type1\_file is also used for OpenType (otf) fonts.

## 4.8.1.14 find\_image\_file

Your callback function should have the following conventions:

```
<string> actual_name = function (<string> asked_name)
```

The asked\_name is an image file. Your return value is used to open a file from the harddisk, so make sure you return something that is considered the name of a valid file by your operating system.

## 4.8.2 File reading callbacks

## 4.8.2.1 open\_read\_file

Your callback function should have the following conventions:

```
 env = function (<string> file_name)
```

Argument:

file\_name

The filename returned by a previous find\_read\_file or the return value of kpse.find\_file() if there was no such callback defined.

Return value:

env

This is a table containing at least one required and one optional callback function for this file. The required field is reader and the associated function will be called once for each new line to be read, the optional one is close that will be called once when LuaTFX is done with the file.

LuaTEX never looks at the rest of the table, so you can use it to store your private per-file data. Both the callback functions will receive the table as their only argument.

#### 4.8.2.1.1 reader

LuaTFX will run this function whenever it needs a new input line from the file.

```
function( env)
    return <string> line
end
```

Your function should return either a string or nil. The value nil signals that the end of file has occurred, and will make TEX call the optional close function next.

#### 4.8.2.1.2 close

LuaTFX will run this optional function when it decides to close the file.

```
function( env)
    return
end
```

Your function should not return any value.

#### 4.8.2.2 General file readers

There is a set of callbacks for the loading of binary data files. These all use the same interface:

```
function(<string> name)
    return <boolean> success, <string> data, <number> data_size
end
```

The name will normally be a full path name as it is returned by either one of the file discovery callbacks or the internal version of kpse.find\_file().

```
success
```

Return false when a fatal error occured (e.g. when the file cannot be found, after all). data

The bytes comprising the file.

data\_size

The length of the data, in bytes.

Return an empty string and zero if the file was found but there was a reading problem.

The list of functions is as follows:

```
ofm or tfm files
read font file
read_vf_file
                       virtual fonts
read ocp file
                       ocp files
                       map files
read_map_file
read_enc_file
                       encoding files
read_sfd_file
                       subfont definition files
                       pk bitmap files
read_pk_file
                       embedded files (\pdfobj file ...)
read data file
read_truetype_file
                       TrueTupe font files
read_type1_file
                       Type1 font files
                       OpenTupe font files
read opentype file
```

## 4.8.3 Data processing callbacks

## 4.8.3.1 process\_input\_buffer

This callback allows you to change the contents of the line input buffer just before LuaTEX actually starts looking at it.

```
function(<string> buffer)
    return <string> adjusted_buffer
end
```

If you return nil, LuaTEX will pretend like your callback never happened. You can gain a small amount of processing time from that.

## 4.8.3.2 token\_filter

This callback allows you to replace the way LuaTFX fetches lexical tokens.

```
function()
    return  token
end
```

The calling convention for this callback is a bit more complicated than for most other callbacks. The function should either return a Lua table representing a valid to-be-processed token or tokenlist, or something else like nil or an empty table.

If your Lua function does not return a table representing a valid token, it will be immediately called again, until it eventually does return a useful token or tokenlist (or until you reset the callback value to nil). See the description of token for some handy functions to be used in conjunction with this callback.

If your function returns a single usable token, then that token will be processed by LuaTEX immediately. If the function returns a token list (a table consisting of a list of consecutive token tables), then that list will be pushed to the input stack at a completely new token list level, with its token type set to 'inserted'. In either case, the returned token(s) will not be fed back into the callback function.

## 4.8.4 Node list processing callbacks

The description of nodes and node lists is in chapter 8.

## 4.8.4.1 buildpage\_filter

This callback is called whenever LuaTEX is ready to move stuff to the main vertical list. You can use this callback to do specialized manipulation of the page building stage like imposition or column balancing.

```
function(<string> extrainfo)
end
```

The string extrainfo gives some additional information about what TEX's state is with respect to the 'current page'. The possible values are:

value	explanation
alignment	a (partial) alignment is being added
after_output	an output routine has just finished
box	a typeset box is being added
new_graf	the beginning of a new paragraph
vmode_par	\par was found in vertical mode
hmode_par	\par was found in horizontal mode
insert	an insert is added
penalty	a penalty (in vertical mode)
before_display	immediately before a display starts
after_display	a display is finished
end	LuaT <sub>E</sub> X is terminating (it's all over)

## 4.8.4.2 pre\_linebreak\_filter

This callback is called just before LuaTEX starts converting a list of nodes into a stack of \hboxes. The removal of a possible final skip and the subsequent insertion of \parfillskip has not happened yet at that moment.

```
function(<node> head, <string> groupcode)
    return true | false | <node> newhead
end
```

The string called groupcode identifies the nodelist's context within TEX's processing. The range of possibilities is given in the table below, but not all of those can actually appear in pre\_linebreak\_filter, some are for the hpack\_filter and vpack\_filter callbacks that will be explained in the next two paragraphs.

value	explanation
<empty></empty>	main vertical list
hbox	\hbox in horizontal mode

adjusted\_hbox \hbox in vertical mode
vbox
vtop \vtop

align \halign or \valign

vcenter \vcenter

local\_box \localleftbox or \localrightbox

split\_off top of a \vsplit
split\_keep remainder of a \vsplit

align\_set alignment cell
fin\_row alignment row

## 4.8.4.3 linebreak\_filter

This callback replaces LuaT<sub>E</sub>X's line breaking algorithm.

```
function(<node> head, <boolean> is_display)
    return <node> newhead
end
```

The returned node is the head of the list that will be added to the main vertical list, the boolean argument is true if this paragraph is interrupted by a following math display.

If you return something that is not a <node>, LuaTEX will apply the internal linebreak algorithm on the list that starts at <head>.

## 4.8.4.4 post\_linebreak\_filter

This callback is called just after LuaTFX has converted a list of nodes into a stack of \hboxes.

```
function(<node> head, <string> groupcode)
   return true | false | <node> newhead
end
```

## 4.8.4.5 hpack\_filter

This callback is called when TEX is ready to start boxing some horizontal mode material. Math items and line boxes are ignored at the moment.

```
function(<node> head, <string> groupcode, <number> size, <string> packtype)
   return true | false | <node> newhead
end
```

The packtype is either additional or exactly. If additional, then the size is a \hbox spread ... argument. If exactly, then the size is a \hbox to .... In both cases, the number is in scaled points.

## 4.8.4.6 vpack\_filter

This callback is called when TEX is ready to start boxing some vertical mode material. Math displays are ignored at the moment.

This function is very similar to the hpack\_filter. Besides the fact that it is called at different moments, there is an extra variable that matches TFX's \maxdepth setting.

```
function(<node> head, <string> groupcode, <number> size, <string> packtype,
<number> maxdepth)
   return true | false | <node> newhead
end
```

## 4.8.4.7 pre\_output\_filter

This callback is called when TEX is ready to start boxing the box 255 for \output.

```
function(<node> head, <string> groupcode, <number> size, <string> packtype,
<number> maxdepth)
    return true | false | <node> newhead
end
```

## **4.8.4.8** hyphenate

```
function(<node> head, <node> tail)
end
```

No return values. This callback has to insert discretionary nodes in the node list it receives.

### 4.8.4.9 ligaturing

```
function(<node> head, <node> tail)
end
```

No return values. This callback has to apply ligaturing to the node list it receives.

You don't have to worry about return values because the head node that is passed on to the callback is quaranteed not to be a qlyph\_node (if need be, a temporary node will be prepended), and therefore it cannot be affected by the mutations that take place. After the callback, the internal value of the 'tail of the list' will be recalculated.

The next of head is guaranteed to be non-nil.

The next of tail is guaranteed be nil, and therefore the second callback argument can often be ignored. It is provided for orthogonality, and because it can sometimes be handy when special processing has to take place.

#### **4.8.4.10** kerning

```
function(<node> head, <node> tail) end
```

No return values. This callback has to apply kerning between the nodes in the node list it receives. See ligaturing for calling conventions.

## 4.8.4.11 mlist\_to\_hlist

This callback replaces LuaTFX's math list to node list conversion algorithm.

```
function(<node> head, <string> displaytype, <boolean> need_penalties)
    return <node> newhead
end
```

The returned node is the head of the list that will be added to the vertical or horizontal list, the string argument is either 'text' or 'display' depending on the current math mode, the boolean argument is true if penalties have to be inserted in this list, false otherwise.

#### Information reporting callbacks 4.8.5

#### 4.8.5.1 start run

```
function()
```

Replaces the code that prints LuaTFX's banner.

## 4.8.5.2 stop\_run

#### function()

Replaces the code that prints LuaTFX's statistics and 'output written to' messages.

### 4.8.5.3 start\_page\_number

#### function()

Replaces the code that prints the [ and the page number at the begin of \shipout. This callback will also override the printing of box information that normally takes place when \tracingoutput is positive.

#### 4.8.5.4 stop\_page\_number

#### function()

Replaces the code that prints the ] at the end of \shipout.

## 4.8.5.5 show\_error\_hook

```
function()
    return
end
```

This callback is run from inside the TEX error function, and the idea is to allow you to do some extra reporting on top of what TEX already does (none of the normal actions are removed). You may find some of the values in the status table useful.

#### message

is the formal error message  $T_E X$  has given to the user. (the line after the '!). indicator

is either a filename (when it is a string) or a location indicator (a number) that can mean lots of different things like a token list id or a \read number.

#### lineno

is the current line number.

This is an investigative item for 'testing the water' only. The final goal is the total replacement of TEX's error handling routines, but that needs lots of adjustments in the web source because TEX deals with errors in a somewhat haphazard fashion. This is why the exact definition of indicator is not given here.

## 4.8.6 Font-related callbacks

## 4.8.6.1 define\_font

```
function(<string> name, <number> size, <number> id) return  font end
```

The string name is the filename part of the font specification, as given by the user.

The number **size** is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the font table that is to be returned is explained in **chapter 7**. That table is saved internally, so you can put extra fields in the table for your later Lua code to use.

# 4.9 The lua library

This library contains one read-only item:

```
<string> s = lua.version
```

This returns a LuaTEX version identifier string. The value is currently lua.version, but it is soon to be replaced by something more elaborate.

## 4.9.1 LUA bytecode registers

Lua registers can be used to communicate Lua functions across Lua chunks. The accepted values for assignments are functions and nil. Likewise, the retrieved value is either a function or nil.

```
lua.bytecode[n] = function () .. end
lua.bytecode[n]()
```

The contents of the lua.bytecode array is stored inside the format file as actual Lua bytecode, so it can also be used to preload Lua code.

Note: The function must not contain any upvalues. Currently, functions containing upvalues can be stored (and their upvalues are set to nil), but this is an artefact of the current Lua implementation and thus subject to change.

The associated function calls are

```
function f = lua.getbytecode(<number> n)
lua.setbytecode(<number> n, <function> f)
```

Note: Since a Lua file loaded using loadfile(filename) is essentially an anonymous function, a complete file can be stored in a bytecode register like this:

```
lua.bytecode[n] = loadfile(filename)
```

Now all definitions (functions, variables) contained in the file can be created by executing this bytecode register:

```
lua.bytecode[n]()
```

Note that the path of the file is stored in the Lua bytecode to be used in stack backtraces and therefore dumped into the format file if above code is used in iniTFX. If it contains private information, i.e. the user name, this information is then contained in the format file as well. This should be kept in mind when preloading files into a bytecode register in iniTFX.

## 4.9.2 LUA chunk name registers

There is an array of 65536 (0-65535) potential chunk names for use with the \directlua and \latelua primitives.

```
lua.name[<number> n] = <string> s
<string> s = lua.name[<number n>]
```

If you want to unset a lua name, you can assign nil to it.

# 4.10 The kpse library

This library provides an interface to the kpathsea file search method.

Before the search library can be used at all, its database has to be initialized. When LuaTFX is used to typeset documents, this happens automatically (that is, unless explicitly prohibited by the user's startup script. See section 3.1 for more details). In TEXLua mode, the initialization has to be done explicitly via the kpse.set program name function.

## 4.10.1 kpse.set program name

Sets the kpathsea executable (and optionally program) name.

```
kpse.set_program_name(<string> name)
kpse.set_program_name(<string> name, <string> progname)
```

The second argument controls the use of the 'dotted' values in the texmf.cnf configuration file, and defaults to the first argument.

## 4.10.2 kpse.find\_file

The most often used function in the library is find\_file:

```
<string> f = kpse.find_file(<string> filename)
<string> f = kpse.find_file(<string> filename, <string> ftype)
<string> f = kpse.find_file(<string> filename, <boolean> mustexist)
<string> f = kpse.find_file(<string> filename, <string> ftype, <boolean>
mustexist)
<string> f = kpse.find_file(<string> filename, <string> ftype, <number> dpi)
Arguments:
filename
   the name of the file you want to find, with or without extension.
ftupe
   maps to the -format argument of kpsewhich. The supported ftype values are the same as the ones
  supported by the standalone kpsewhich program:
'gf'
                                            'tex'
'pk'
                                            'TeX system documentation'
'bitmap font'
                                            'texpool'
'tfm'
                                            'TeX system sources'
'afm'
                                            'PostScript header'
                                            'Troff fonts'
'base'
'bib'
                                            'type1 fonts'
                                            'vf'
'bst'
'cnf'
                                            'dvips config'
'ls-R'
                                            'ist'
'fmt'
                                            'truetype fonts'
'map'
                                            'type42 fonts'
                                            'web2c files'
'mem'
'mf'
                                            'other text files'
'mfpool'
                                            'other binary files'
'mft'
                                            'misc fonts'
'mp'
                                            'web'
'mppool'
                                            'cweb'
'MetaPost support'
                                            'enc files'
'ocp'
                                            'cmap files'
'ofm'
                                            'subfont definition files'
'opl'
                                            'opentype fonts'
'otp'
                                            'pdftex config'
'ovf'
                                            'lig files'
'qvo'
                                            'texmfscripts'
'graphic/figure'
  The default type is tex.
```

#### mustexist

is similar to kpsewhich's -must-exist, and the default is false. If you specify true (or a non-zero integer), then the kpse library will search the disk as well as the ls-R databases. dpi

This is used for the size argument of the formats pk, gf, and bitmap font.

## 4.10.3 kpse.init\_prog

Extra initialization for programs that need to generate bitmap fonts.

```
kpse.init_prog(<string> prefix, <number> base_dpi, <string> mfmode)
kpse.init_prog(<string> prefix, <number> base_dpi, <string> mfmode, <string>
fallback)
```

## 4.10.4 kpse.readable\_file

Test if an (absolute) file name is a readable file

```
<string> f = kpse.readable_file(<string> name)
```

The return value is the actual absolute filename you should use, because the disk name is not always the same as the requested name, due to aliases and system-specific handling under e.g. msdos.

Returns nil if the file does not exist or is not readable.

## 4.10.5 kpse.expand\_path

```
Like kpsewhich's -expand-path:
```

```
<string> r = kpse.expand_path(<string> s)
```

## 4.10.6 kpse.expand\_var

```
Like kpsewhich's -expand-var:
```

```
<string> r = kpse.expand_var(<string> s)
```

## 4.10.7 kpse.expand\_braces

```
Like kpsewhich's -expand-braces:
```

```
<string> r = kpse.expand braces(<string> s)
```

### 4.10.8 kpse.show\_path

```
Like kpsewhich's -show-path:
```

```
<string> r = kpse.show_path(<string> ftype)
```

### 4.10.9 kpse.var\_value

```
Like kpsewhich's -var-value:
```

```
<string> r = kpse.var_value(<string> s)
```

## The status library

This contains a number of run-time configuration items that you may find useful in message reporting, as well as an iterator function that gets all of the names and values as a table.

```
 info = status.list()
```

The keys in the table are the known items, the value is the current value. Almost all of the values in status are fetched through a metatable at run-time whenever they are accessed, so you cannot use pairs on status, but you can use pairs on info, of course. If you do not need the full list, you can also ask for a single item by using its name as an index into status.

The current list is:

key

pdf_gone	written pdf bytes
pdf_ptr	not yet written pdf bytes
dvi_gone	written dvi bytes
dvi_ptr	not yet written dvi bytes
total_pages	number of written pages
output_file_name	name of the pdf or dvi file
log_name	name of the log file
banner	terminal display banner
var_used	variable (one-word) memory in use
dyn_used	token (multi-word) memory in use
str_ptr	number of strings
init_str_ptr	number of iniTEX strings
max_strings	maximum allowed strings
pool_ptr	string pool index
init_pool_ptr	iniT <sub>E</sub> X string pool index
pool_size	current size allocated for string characters
node_mem_usage	a string giving insight into currently used nodes
	pdf_ptr dvi_gone dvi_ptr total_pages output_file_name log_name banner var_used dyn_used str_ptr init_str_ptr max_strings pool_ptr init_pool_ptr pool_size

explanation

indirect\_callbacks number of those that were themselves a result of other callbacks (e.g. file

readers)

## 4.12 The texconfig table

This is a table that is created empty. A startup Lua script could fill this table with a number of settings that are read out by the executable after loading and executing the startup file.

key	type	default	explanation
kpse_init	boolean	true	false totally disables kpathsea initialisation, and enables
			interpretation of the following numeric key-value pairs. (only
			ever unset this if you implement <i>all</i> file find callbacks!)
string_vacancies	number	75000	cf. web2c docs
pool_free	number	5000	cf. web2c docs
${\tt max\_strings}$	number	15000	cf. web2c docs
strings_free	number	100	cf. web2c docs
nest_size	number	50	cf. web2c docs
max_in_open	number	15	cf. web2c docs
param_size	number	60	cf. web2c docs
save_size	number	4000	cf. web2c docs
stack_size	number	300	cf. web2c docs
dvi_buf_size	number	16384	cf. web2c docs
error_line	number	<b>7</b> 9	cf. web2c docs
half_error_line	number	50	cf. web2c docs
max_print_line	number	<b>7</b> 9	cf. web2c docs
ocp_list_size	number	1000	cf. web2c docs
ocp_buf_size	number	1000	cf. web2c docs
ocp_stack_size	number	1000	cf. web2c docs
hash_extra	number	0	cf. web2c docs
pk_dpi	number	<b>7</b> 2	cf. web2c docs
trace_file_names	boolean	true	false disables TEX's normal file open-close feedback (the
			assumption is that callbacks will take care of that)
file_line_error	boolean	false	do file:line style error messages
halt_on_error	boolean	false	abort run on the first encountered error
formatname	string		if no format name was given on the commandline, this key
			will be tested first instead of simply quitting
jobname	string		if no input file name was given on the commandline, this key
			will be tested first instead of simply giving up

**Note:** the numeric values that match web2c parameters are only used if kpse\_init is explicitly set to false. In all other cases, the normal values from texmf.cnf are used.

## 4.13 The font library

The font library provides the interface into the internals of the font system, and also it contains helper functions to load traditional TEX font metrics formats. Other font loading functionality is provided by the fontforge library that will be discussed in the next section.

## 4.13.1 Loading a TFM file

```
 fnt = font.read_tfm(<string> name, <number> s)
```

The number is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the metrics font table that is returned is explained in **chapter 7**.

### 4.13.2 Loading a VF file

```
 vf_fnt = font.read_vf(<string> name, <number> s)
```

The meaning of the number s, and the format of the returned table is similar to the one returned by the read\_tfm() function.

### 4.13.3 The fonts array

The whole table of TFX fonts is accessible from Lua using a virtual array.

```
font.fonts[n] = { ... }
 f = font.fonts[n]
```

See **chapter 7** for the structure of the tables. Because this is a virtual array, you cannot call **pairs** on it, but see below for the **font.each** iterator.

The two metatable functions implementing the virtual array are:

```
 f = font.getfont(<number> n)
font.setfont(<number> n,  f)
```

Also note the following: assignments can only be made to fonts that have already been defined in T<sub>E</sub>X, but have not been accessed *at all* since that definition. This limits the usability of the write access to font.fonts quite a lot, a less stringent ruleset will likely be implemented later.

### 4.13.4 Checking a font's status

You can test for the status of a font by calling this function:

```
<boolean> f = font.frozen(<number> n)
```

The return value is one of true (unassignable), false (can be changed) or nil (not a valid font at all).

### 4.13.5 Defining a font directly

You can define your own font into font.fonts by calling this function:

```
<number> i = font.define( f)
```

The return value is the internal id number of the defined font (the index into font.fonts). If the font creation fails, an error is raised. The table is a font structure, as explained in chapter 7.

### 4.13.6 Projected next font id

```
number i = font.nextid();
```

This returns the font id number that would be returned by a font.define call if it was executed at this spot in the code flow. This is useful for virtual fonts that need to reference themselves.

### 4.13.7 Currently active font

```
<number> i = font.current();
font.current(<number> i);
```

This gets or sets the currently used font number.

#### 4.13.8 Maximum font id

```
<number> i = font.max();
```

This is the largest used index in font.fonts.

### 4.13.9 Iterating over all fonts

```
for i,v in font.each() do
end
```

This is an iterator over each of the defined TFX fonts. The first returned value is the index in font.fonts, the second the font itself, as a Lua table. The indices are listed incrementally, but they do not always form an array of consecutive numbers: in some cases there can be holes in the sequence.

## 4.14 The fontforge library

### 4.14.1 Getting quick information on a font

```
local info = fontforge.info('filename')
```

This function returns either nil, or a table, or an array of small tables (in the case of a TrueType collection). The returned table(s) will contain six fairly interesting information items from the font(s) defined by the file:

```
explanation
key
                type
                string the PostScript name of the font
fontname
                       the formal name of the font
fullname
                string
familyname
                string
                       the family name this font belongs to
                        a string indicating the color value of the font
weight
                string
                        the internal font version
version
                string
italicangle float
                        the slant angle
```

Getting information through this function is (sometimes much) more efficient than loading the font properly, and is therefore handy when you want to create a dictionary of available fonts based on a directory contents.

### 4.14.2 Loading an OPENTYPE or TRUETYPE file

If you want to use an OpenType font, you have to get the metric information from somewhere. Using the fontforge library, the basic way to get that information is thus:

```
function load_font (filename)
  local metrics = nil
  local font = fontforge.open(filename)
  if font then
     metrics = fontforge.to_table(font)
     fontforge.close(font)
  end
  return metrics
end

myfont = load_font('/opt/tex/texmf/fonts/data/arial.ttf')
The main function call is

f, w = fontforge.open('filename')
```

The first return value is a table representation of the font. The second return value is a table containing any warnings and errors reported by fontforge while opening the font. In normal typesetting, you would probably ignore the second argument, but it can be useful for debugging purposes.

For TrueType collections (when filename ends in 'ttc'), you have to use a second string argument to specify which font you want from the collection. Use one of the fullname strings that are returned by fontforge.info for that.

```
f, w = fontforge.open('filename', 'fullname')
```

The font file is parsed and partially interpreted by the font loading routines from FontForge. The file format can be OpenType, TrueType, TrueType Collection, cff, or Type1.

There are a few advantages to this approach compared to reading the actual font file ourselves:

- The font is automatically re-encoded, so that the metrics table for TrueType and OpenType fonts is using Unicode for the character indices.
- Many features are pre-processed into a format that is easier to handle than just the bare tables would be.
- PostScript-based OpenType fonts do not store the character height and depth in the font file, so the character boundingbox has to be calculated in some way.
- In the future, it may be interesting to allow Lua scripts access to the font program itself, perhaps even creating or changing the font.

### 4.14.3 Applying a 'feature file'

You can apply a 'feature file' to a loaded font:

```
fontforge.apply_featurefile(f,'filename')
```

A 'feature file' is a textual representation of the features in an OpenType font. //www.adobe.com/devnet/opentype/afdko/topic\_feature\_file\_syntax.html and http://fontforge.sourceforge .net/featurefile.html for a more detailed description of feature files.

### 4.14.4 Applying an 'AFM file'

You can apply an 'afm file' to a loaded font:

```
fontforge.apply_afmfile(f,'filename')
```

An afm file is a textual representation of (some of) the meta information in a Type1 font. See http://www .adobe.com/devnet/font/pdfs/5004.AFM\_Spec.pdf for more information about afm files.

Note: If you fontforge.open() a Type1 file named font.pfb, the library will automatically search for and apply font.afm if it exists in the same directory as the file font.pfb. In that case, there is no need for an explicit call to apply\_afmfile().

# 4.15 Fontforge font tables

## 4.15.1 Table types

### 4.15.1.1 **Top-level**

The top-level keys in the returned table are (the explanations in this part of the documentation are not yet finished):

key	type	explanation
table_version	number	indicates the metrics version (currently 0.3)
fontname	string	PostScript font name
fullname	string	official font name
familyname	string	family name
weight	string	weight indicator
copyright	string	copyright information
filename	string	the file name
version	string	font version
italicangle	float	slant angle
units_per_em	number	1000 for PostScript-based fonts, usually 2048 for
		TrueType
ascent	number	height of ascender in units_per_em
descent	number	depth of descender in units_per_em
upos	float	
uwidth	float	
uniqueid	number	
glyphcnt	number	number of included glyphs
glyphs	array	
glyphmax	number	maximum used index the glyphs array
hasvmetrics	number	
onlybitmaps	number	
serifcheck	number	
isserif	number	
issans	number	
encodingchanged	number	
strokedfont	number	
use_typo_metrics	number	
weight_width_slope_only	number	
head_optimized_for_cleartype	number	
uni_interp	enum	unset, none, adobe, greek, japanese, trad_chi-
		nese, simp_chinese, korean, ams
origname	string	the file name, as supplied by the user

table mapprivate table xuid string pfminfo table names table cidinfo table subfonts array commments string fontlog string cvt\_names string anchor\_classes table ttf\_tables table ttf\_tab\_saved table kerns table table vkerns table texdata table lookups gpos table table gsub table smtable features mm table chosenname string macstyle number fondname string design\_size number fontstyle\_id number fontstyle\_name table design\_range\_bottom number design\_range\_top number strokewidth float mark\_classes array mark\_class\_names array creationtime number modificationtime number os2\_version number sfd\_version number math table validation\_state table horiz\_base table vert base table extrema\_bound number

### 4.15.1.2 Glyph items

The glyphs is an array containing the per-character information (quite a few of these are only present if nonzero).

key	type	explanation
name	string	the glyph name
unicode	number	unicode code point, or -1
boundingbox	array	array of four numbers
width	number	only for horizontal fonts
vwidth	number	only for vertical fonts
lsidebearing	number	only if nonzero and not equal to boundingbox[1]
class	string	one of "automatic", "none" ,"base", "ligature","mark", "component"
kerns	array	only for horizontal fonts, if set
vkerns	array	only for vertical fonts, if set
dependents	array	linear array of glyph name strings, only if nonempty
lookups	table	only if nonempty
ligatures	table	only if nonempty
anchors	table	only if set
comment	string	only if set
tex_height	number	only if set
tex_depth	number	only if set
<pre>italic_correction</pre>	number	only if set
top_accent	number	only if set
is_extended_shape	number	only if this character is part of a math extension list
altuni	table	alternate Unicode items
vert_variants	table	
horiz_variants	table	
mathkern	table	

The kerns and vkerns are linear arrays of small hashes:

key	type	explanation
char	string	
off	number	
lookup	string	

The lookups is a hash, based on lookup subtable names, with the value of each key inside that a linear array of small hashes:

key	type	explanation	
type	enum	position, pair, substitution, alternate, multiple, ligature,	
		lcaret, kerning, vkerning, anchors, contextpos, contextsub,	
		chainpos, chainsub, reversesub, max, kernback, vkernback	
specification	table	extra data	

For the first seven values of type, there can be additional sub-information, stored in the sub-table specification:

```
value
                       explanation
                type
position
                table
                      a table of the offset_specs type
                table
                      one string: paired, and an array of one or two offset_specs tables: off-
pair
substitution table one string: variant
alternate
                table one string: components
                table one string: components
multiple
                table two strings: components, char
ligature
lcaret
                array linear array of numbers
```

Tables for offset\_specs contain up to four number-valued fields: x (a horizontal offset), y (a vertical offset), y (an advance width correction) and y (an advance height correction).

The ligatures is a linear array of small hashes:

key	type	explanation
lig	table	uses the same substructure as a single possub item
char	string	
components	array	linear array of named components
ccnt	number	

The anchor table is indexed by a string signifying the anchor type, which is one of

key	type	explanation
mark	table	placement mark
basechar	table	mark for attaching combining items to a base char
baselig	table	mark for attaching combining items to a ligature
basemark	table	generic mark for attaching combining items to connect to
centry	table	cursive entry point
cexit	table	cursive exit point

The content of these is an short array of defined anchors, with the entry keys being the anchor names. For all except baselig, the value is a single table with this definition:

key	type	explanation
X	number	x location
У	number	y location
ttf_pt_index	number	truetype point index, only if given

For baselig, the value is a small array of such anchor sets sets, one for each constituent item of the ligature.

For clarification, an anchor table could for example look like this:

```
['anchor'] = {
      ['basemark'] = {
            ['Anchor-7'] = { ['x']=170, ['y']=1080 }
      },
      ['mark'] = {
            ['Anchor-1'] = { ['x']=160, ['y']=810 },
            ['Anchor-4'] = { ['x']=160, ['y']=800 }
      },
      ['baselig'] = {
            [1] = { ['Anchor-2'] = { ['x']=160, ['y']=650 } },
      [2] = { ['Anchor-2'] = { ['x']=460, ['y']=640 } }
      }
    }
}
```

### 4.15.1.3 map table

The top-level map is a list of encoding mappings. Each of those is a table itself.

key	type	explanation
enccount	number	
encmax	number	
backmax	number	
remap	table	
map	array	non-linear array of mappings
backmap	array	non-linear array of backward mappings
enc	table	

The remap table is very small:

key	type	explanation
firstenc	number	
lastenc	number	
infont	number	

The enc table is a bit more verbose:

type	explanation
string	
number	
number	
array	of Unicode position numbers
array	of PostScript glyph names
number	
number	
number	
	string number number array array number number

has\_1byte number has\_2byte number is\_unicodebmp number only if nonzero only if nonzero is\_unicodefull number is\_custom number only if nonzero is\_original number only if nonzero number only if nonzero is\_compact is\_japanese number only if nonzero is\_korean number only if nonzero is\_tradchinese number only if nonzero [name?] is\_simplechinese number only if nonzero low\_page number high\_page number iconv\_name string iso\_2022\_escape string

### 4.15.1.4 private table

This is the font's private PostScript dictionary, if any. Keys and values are both strings.

#### 4.15.1.5 cidinfo table

key	type	explanation
registry	string	
ordering	string	
supplement	number	
version	number	

### 4.15.1.6 pfminfo table

The pfminfo table contains most of the OS/2 information:

key	type	explanation
pfmset	number	
winascent_add	number	
windescent_add	number	
hheadascent_add	number	
hheaddescent_add	number	
typoascent_add	number	
typodescent_add	number	
subsuper_set	number	
panose_set	number	
hheadset	number	

vheadset number pfmfamily number weight number width number avgwidth number firstchar number lastchar number fstype number linegap number vlinegap number hhead\_ascent number hhead\_descent number hhead\_descent number os2\_typoascent number os2\_typodescent number number os2\_typolinegap os2\_winascent number os2\_windescent number os2 subxsize number os2\_subysize number os2\_subxoff number os2\_subyoff number number os2\_supxsize os2\_supysize number os2\_supxoff number os2\_supyoff number os2\_strikeysize number os2\_strikeypos number number os2\_family\_class os2\_xheight number number os2\_capheight os2\_defaultchar number os2\_breakchar number os2\_vendor string codepages table A two-number array of encoded code pages A four-number array of encoded unicode ranges unicoderages table table panose

The panose subtable has exactly 10 string keys:

key	type	explanation
familytype	string	Values as in the OpenType font specification: Any, No Fit, Text and
		Display, Script, Decorative, Pictorial
serifstyle	string	See the OpenType font specification for values
weight	string	id.

```
proportion
                   string id.
contrast
                    string
                          id.
strokevariation string
                          id.
armstyle
                    string
                          id.
letterform
                   string
                          id.
midline
                    string
                          id.
xheight
                          id.
                    string
```

#### 4.15.1.7 names table

Each item has two top-level keys:

type explanation key lang string language for this entry table names

The names keys are the actual TrueType name strings. The possible keys are:

#### key explanation

copyright family subfamily uniqueid fullname version postscriptname trademark manufacturer designer descriptor venderurl designerurl license licenseurl idontknow preffamilyname prefmodifiers compatfull sampletext cidfindfontname wwsfamily wwssubfamily

#### 4.15.1.8 anchor\_classes table

The anchor\_classes classes:

key type explanation

name string a descriptive id of this anchor class

lookup string

type string one of mark, mkmk, curs, mklg

#### 4.15.1.9 gpos table

Th gpos table has one array entry for each lookup. (The gpos\_ prefix is somewhat redundant.)

key type explanation

type string one of gpos\_single, gpos\_pair, gpos\_cursive, gpos\_mark2base, gpos\_mark2lig-

ature, gpos\_mark2mark, gpos\_context, gpos\_contextchain

flags table name string features array subtables array

The flags table has a true value for each of the lookup flags that is actually set:

key type explanation

r21 boolean ignorebaseglyphs boolean ignoreligatures boolean ignorecombiningmarks boolean

The features subtable of gpos has:

key type explanation

tag string scripts table

ismac number (only if true)

The scripts table within features has:

key type explanation

script string

langs array of strings

The subtables table has:

key type explanation

name string

```
suffix
                     string
                              (only if used)
anchor_classes
                     number
                             (only if used)
                             (only if used)
vertical_kerning number
kernclass
                     table
                              (only if used)
```

The kernclass with subtables table has:

key	type	explanation
firsts	array of strings	
seconds	array of strings	
lookup	string	associated lookup
offsets	array of numbers	

### 4.15.1.10 qsub table

This has identical layout to the gpos table, except for the type:

```
key
      type
            explanation
type string one of gsub_single, gsub_multiple, gsub_alternate, gsub_ligature, gsub_con-
            text, gsub_contextchain, gsub_reversecontextchain
```

### 4.15.1.11 ttf\_tables and ttf\_tab\_saved tables

```
key
         type
                 explanation
tag
         string
         number
len
maxlen number
         number
data
```

#### 4.15.1.12 sm table

key	type	explanation
type	string	one of "indic", "context", "lig", "simple", "insert", "kern"
lookup	string	
flags	table	a set of boolean values with the keys : "vert", "descending", "always"
classes	table	an array of named classes
state	table	

The **state** table has:

key	type	explanation
next	number	
flags	number	

context table A small table that has 'mark' and 'cur' as possible keys, with the values being

lookup names. Only applies if the sm.type = context.

insert table A small table that has 'mark' and 'cur' as possible keys, with the values strings.

Only applies if the sm.type = insert.

kern table A small array with kern data. Only applies if the sm.type = kern.

#### 4.15.1.13 features table

key type explanation

feature number ismutex number default\_setting number strid number

featname table A set of mac names. macnames are like offnames except that they also

have an 'enc' field

table settings

The settings are:

key type explanation

number setting number strid initially\_enabled number

table setname A set of mac names. macnames are like offnames except that they

also have an 'enc' field

#### 4.15.1.14 mm table

key type explanation axes table array of axis names

instance\_count number

array of instance positions (#axes \* instances ) positions table

array of default weights for instances defweights table

cdv string ndv string table axismaps named\_instance\_count number named\_instances table number apple

The axismaps:

explanation key type

blends table an array of blend points an array of design values designs table

number min def number number max

axisnames table a set of mac names

The named\_instances is an array of instances:

key type explanation

table a set of mac names names coords table an array of coordinates

### 4.15.1.17 horiz\_base and vert\_base table

key type explanation

tags table an array of script list tags

table scripts

The scripts subtable:

key type explanation

baseline table default baseline number table lang

The lang subtable:

key type explanation string a script tag tag

number ascent descent number features table

The features points to an array of tables with the same layout except that in those nested tables, the tag represents a language.

#### 4.15.1.18 altuni table

An array of alternate Unicode values. Inside that array are hashes with:

explanation key type

unicode number variant number

#### 4.15.1.19 vert\_variants and horiz\_variants table

key type explanation

variants string italic\_correction number parts table

The parts table is an array of smaller tables:

key type explanation

component string extender number start number

end number advance number

#### 4.15.1.20 mathkern table

explanation key type top\_right table bottom\_right table table top left bottom\_left table

Each of the subtables is an array of small hashes with two keys:

explanation key type height number number kern

#### 4.15.1.21 kerns table

Substructure is identical to the per-glyph subtable.

#### 4.15.1.22 vkerns table

Substructure is identical to the per-glyph subtable.

#### 4.15.1.23 texdata table

key explanation type string unset, text, math, mathext type 22 font numeric parameters params array

#### 4.15.1.24 lookups table

Top-level lookups is quite different from the ones at character level. The keys in this hash are strings, the values the actual lookups, represented as dictionary tables.

key	type	explanation
type	number	
format	enum	one of glyphs, class, coverage, reversecoverage
tag	string	
current_class	array	
before_class	array	

after\_class array

rules array an array of rule items

Rule items have one common item and one specialized item:

key	type	explanation
lookups	array	a linear array of lookup names
glyph	array	only if the parent's format is glyph
class	array	only if the parent's format is glyph
coverage	array	only if the parent's format is glyph
reversecoverage	arrau	only if the parent's format is glyph

#### A glyph table is:

```
key
        type
               explanation
names string
back
        string
fore
        string
```

#### A class table is:

key	type	explanation
current	array	of numbers
before	array	of numbers
after	array	of numbers

#### coverage:

key	type	explanation
current	array	of strings
before	array	of strings
after	array	of strings

#### reversecoverage:

key	type	explanation
current	array	of strings
before	array	of strings
after	array	of strings
replacements	strina	

## 4.16 The lang library

This library provides the interface to LuaTeX's structure representing a language, and the associated functions.

```
<language> 1 = lang.new()
<language> 1 = lang.new(<number> id)
```

This function creates a new userdata object. An object of type <language> is the first argument to most of the other functions in the lang library. These functions can also be used as if they were object methods, using the colon syntax.

Without an argument, the next available internal id number will be assigned to this object. With argument, an object will be created that links to the internal language with that id number.

```
<number> n = lang.id(<language> 1)
```

returns the internal \language id number this object refers to.

```
<string> n = lang.hyphenation(<language> 1)
lang.hyphenation(<language> 1, <string> n)
```

Either returns the current hyphenation exceptions for this language, or adds new ones. The syntax of the string is explained in the next chapter, section 6.3.

```
lang.clear_hyphenation(<language> 1)
```

Clears the exception dictionary for this language.

```
<string> n = lang.clean(<string> o)
```

Creates a hypenation key from the supplied hyphenation value. The syntax of the argument string is explained in the next chapter, section 6.3. This function is useful if you want to do something else based on the words in a dictionary file, like spell-checking.

```
<string> n = lang.patterns(<language> 1)
lang.patterns(<language> 1, <string> n)
```

Adds additional patterns for this language object, or returns the current set. The syntax of this string is explained in the next chapter, section 6.3.

```
lang.clear_patterns(<language> 1)
```

Clears the pattern dictionary for this language.

```
<number> n = lang.prehyphenchar(<language> 1)
lang.prehyphenchar(<language> 1, <number> n)
```

Gets or sets the 'pre-break' hyphen character for implicit hyphenation in this language (initially the hyphen, decimal 45).

```
<number> n = lang.posthyphenchar(<language> 1)
lang.posthyphenchar(<language> 1, <number> n)
```

Gets or sets the 'post-break' hyphen character for implicit hyphenation in this language (initially null, decimal 0, indicating emptyness).

```
<number> n = lang.preexhyphenchar(<language> 1)
lang.preexhyphenchar(<language> 1, <number> n)
```

Gets or sets the 'pre-break' hyphen character for explicit hyphenation in this language (initially null, decimal 0, indicating emptyness).

```
<number> n = lang.postexhyphenchar(<language> 1)
lang.postexhyphenchar(<language> 1, <number> n)
```

Gets or sets the 'post-break' hyphen character for explicit hyphenation in this language (initially null, decimal 0, indicating emptyness).

```
<boolean> success = lang.hyphenate(<node> head)
<boolean> success = lang.hyphenate(<node> head, <node> tail)
```

Inserts hyphenation points (discretionary nodes) in a node list. If tail is given as argument, processing stops on that node. Currently, succes is always true if head (and tail, if specified) are proper nodes, regardless of possible other errors.

Hyphenation works only on 'characters', a special subtype of all the glyph nodes with the node subtype having the value 1. Glyph modes with different subtypes are not processed. See **section 6.1** for more details.

## 5 Math

The handling of mathematics in LuaTEX differs quite a bit from how TEX82 (and therefore pdfTEX) handles math. First, LuaTEX adds primitives and extends some others so that Unicode input can be used easily. Second, all of TEX82's internal special values (for example for operator spacing) have been made accessible and changeable via control sequences. Third, there are extensions that make it easier to use OpenType math fonts. And finally, there are some extensions that have been proposed in the past that are now added to the engine.

### 5.1 Unicode math characters

Character handling is now extended up to the full Unicode range. The extension from 8-bit to 16-bit was already present in Aleph by means of a set of extra primitives starting with the  $\o$  prefix, the extension to full Unicode (the  $\U$  prefix) is compatible with XaTFX.

The math primitives from TEX and Aleph are kept as they are, except for the ones that convert from input to math commands: mathcode, omathcode, delcode, and odelcode. These four now allow for a 21-bit character argument on the left hand side of the equals sign.

Some of the Aleph math primitives and the new LuaTEX primitives read more than one separate value. This is shown in the tables below by a plus sign in the second column.

The input for such primitives would look like this:

```
\def\overbrace {\Umathaccent 0 1 "23DE }
```

Altered TFX82 primitives:

primitive value range (in hex) \mathcode 0-10FFFF = 0-8000\delcode 0-10FFFF = 0-FFFFFF

Unaltered:

primitive value range (in hex)

\mathchardef 0-8000 \mathchar 0-7FFF \mathaccent 0-7FFFFF \delimiter 0-7FFFFFF \radical 0-7FFFFFF

Altered Aleph primitives:

primitive value range (in hex) 0-10FFFF = 0-8000000

\odelcode 0-10FFFF = 0+0-FFFFFF+FFFFF

#### Unaltered:

primitive value range (in hex)

\odelimiter 0+0-7FFFFFF + FFFFFF \oradical 0+0-7FFFFFF + FFFFFF

New primitives that are compatible with  $X \supseteq T \models X$ :

primitive value range (in hex)  $0+0+0-7+FF+10FFFF^1$ 

\Umathcode  $0-10FFFF = 0+0+0-7+FF+10FFFF^1$ 

\Udelcode  $0-10FFFF = 0+0-FF+10FFFF^2$ 

 $\verb|\Umathcharnum| -80000000-7FFFFFF|^3$ 

Note 1: \Umathchardef<csname>="8"0"0 and \Umathchardef<number>="8"0"0 are also accepted.

Note 2: The new primitives that deal with delimiter-style objects do not set up a 'large family'. Selecting a suitable size for display purposes is expected to be dealt with by the font via the \Umathoperatorsize parameter (more information a following section).

Note 3: For these three primitives, all information is packed into a single signed integer. For the first two (\Umathcharnum and \Umathcodenum), the lowest 21 bits are the character code, the 3 bits above that represent the math class, and the family data is kept in the topmost bits (This means that the values for math families 128–255 are actually negative). For \Udelcodenum there is no math class; the math family information is stored in the bits directly on top of the character code. Using these three commands is not as natural as using the two- and three-value commands, so unless you know exactly what you are doing and absolutely require the speedup resulting from the faster input scanning, it is better to use the verbose commands instead.

New primitives that exist in LuaTFX only (all of these will be explained in following sections):

primitive value range (in hex) 0+0+0-7+FF+10FFFF

 $\U$ root  $0+0-FF+10FFFF^2$  $\U$ overdelimiter  $0+0-FF+10FFFF^2$  $\U$ underdelimiter  $0+0-FF+10FFFF^2$ 

## 5.2 Cramped math styles

LuaTEX has four new primitives to set the cramped math styles directly:

\crampeddisplaystyle \crampedtextstyle \crampedscriptstyle \crampedscriptscriptstyle

These additional commands are not all that valuable on their own, but they come in handy as arguments to the math parameter settings that will be added shortly.

## 5.3 Math parameter settings

In LuaTEX, the font dimension parameters that TEX used in math typesetting are now accessible via primitive commands. In fact, refactoring of the math engine has resulted in many more parameters than were accessible before.

primitive name	description
\Umathquad	the width of 18mu's
\Umathaxis	height of the vertical center axis of the math formula above the
	baseline
\Umathoperatorsize	minimum size of large operators in display mode
\Umathoverbarkern	vertical clearance above the rule
\Umathoverbarrule	the width of the rule
\Umathoverbarvgap	vertical clearance below the rule
\Umathunderbarkern	vertical clearance below the rule
\Umathunderbarrule	the width of the rule
\Umathunderbarvgap	vertical clearance above the rule
\Umathradicalkern	vertical clearance above the rule
\Umathradicalrule	the width of the rule
\Umathradicalvgap	vertical clearance below the rule
\Umathradicaldegreebefore	the forward kern that takes place before placement of the radical
	degree
\Umathradicaldegreeafter	the backward kern that takes place after placement of the radical
	degree
\Umathradicaldegreeraise	this is the percentage of the total height and depth of the radical
	sign that the degree is raised by. It is expressed in percents, so
	60% is expressed as the integer 60.
\Umathstackvgap	vertical clearance between the two elements in a \atop stack
\Umathstacknumup	numerator shift upward in \atop stack
\Umathstackdenomdown	denominator shift downward in \atop stack
\Umathfractionrule	the width of the rule in a \over
\Umathfractionnumvgap	vertical clearance between the numerator and the rule

\Umathfractionnumup numerator shift upward in \over \Umathfractiondenomvgap vertical clearance between the denominator and the rule denominator shift downward in \over \Umathfractiondenomdown minimum delimiter size for \...withdelims \Umathfractiondelsize \Umathlimitabovevgap vertical clearance for limits above operators \Umathlimitabovebgap vertical baseline clearance for limits above operators \Umathlimitabovekern space reserved at the top of the limit \Umathlimitbelowvgap vertical clearance for limits below operators \Umathlimitbelowbgap vertical baseline clearance for limits below operators \Umathlimitbelowkern space reserved at the bottom of the limit \Umathoverdelimitervgap vertical clearance for limits above delimiters vertical baseline clearance for limits above delimiters \Umathoverdelimiterbgap \Umathunderdelimitervgap vertical clearance for limits below delimiters \Umathunderdelimiterbgap vertical baseline clearance for limits below delimiters \Umathsubshiftdrop subscript drop for boxes and subformulas \Umathsubshiftdown subscript drop for characters \Umathsupshiftdrop superscript drop (raise, actually) for boxes and subformulas \Umathsupshiftup superscript raise for characters \Umathsubsupshiftdown subscript drop in the presence of a superscript \Umathsubtopmax the top of standalone subscripts cannot be higher than this above the baseline \Umathsupbottommin the bottom of standalone superscripts cannot be less than this above the baseline \Umathsupsubbottommax the bottom of the superscript of a combined super- and subscript be at least as high as this above the baseline

vertical clearance between super- and subscript

additional space added after a super- or subscript

minimum overlap between parts in an extensible recipe

Each of the parameters in this section can be set by a command like this:

\Umathquad\displaystyle=1em

\Umathsubsupvgap

\Umathspaceafterscript

\Umathconnectoroverlapmin

they obey grouping, and you can use \the\Umathquad\displaystyle if needed.

### 5.4 Font-based Math Parameters

While it is nice to have these math parameters available for tweaking, it would be tedious to have to set each of them by hand. For this reason, LuaTEX initializes a bunch of these parameters whenever you assign a font identifier to a math family based on either the traditional math font dimensions in the font (for assignments to math family 2 and 3 using tfm-based fonts like cmsy and cmex), or based on the named values in a potential MathConstants table when the font is loaded via Lua. If there is a MathConstants table, this takes precedence over font dimensions, and in that case no attention is

paid to which family is being assigned to: the MathConstants tables in the last assigned family sets all parameters.

In the table below, the one-letter style abbreviations and symbolic tfm font dimension names match those using in the TEXbook. Assignments to \textfont set the values for the cramped and uncramped display and text styles. Use \scriptfont for the script styles, and \scriptscriptfont for the scriptscript styles (totalling eight parameters for three font sizes). In the tfm case, assignments only happen in family 2 and family 3 (and of course only for the parameters for which there are font dimensions).

3 ,	9	'	,
variable	style	default value opentype	default value tfm
\Umathaxis	_	AxisHeight	axis_height
\Umathoperatorsize	D, D'	MinimumDisplayOperatorHeight	6
\Umathfractiondelsize	D, D'	01	delim1
п	T, T', S, S', SS, SS'	01	delim2

\Umathradicalvgap	D, D'	RadicalDisplayStyleVerticalGap	(default_rule_thickness+
	T TI O OI OO OOI	B 10 10 10	(abs(math_x_height)/4)) <sup>3</sup>
11	T, T', S, S', SS, SS'	RadicalVerticalGap	(default_rule_thickness+
			(abs(default_rule_thickness)/4)) <sup>3</sup>
\Umathradicaldegreebefore	-	RadicalKernBeforeDegree	$<$ not set $>^2$
\Umathradicaldegreeafter	_	RadicalKernAfterDegree	$\langle \text{not set} \rangle^2$
\Umathradicaldegreeraise	_	RadicalDegreeBottomRaisePercent	$<$ not set $>^{2,7}$
\Umathspaceafterscript	_	SpaceAfterScript	script_space <sup>4</sup>
\Umathstackdenomdown	D, D'	StackBottomDisplayStyleShiftDown	denom1
	T, T', S, S', SS, SS'	StackBottomShiftDown	denom2
\Umathstacknumup	D, D'	StackTopDisplayStyleShiftUp	num1
П	T, T', S, S', SS, SS'	StackTopShiftUp	num3
\Umathstackvgap	D, D'	StackDisplayStyleGapMin	7*default_rule_thickness
П	T, T', S, S', SS, SS'	StackGapMin	3*default_rule_thickness
\Umathsubshiftdown	-	SubscriptShiftDown	sub1
\Umathsubshiftdrop	-	SubscriptBaselineDropMin	sub_drop
\Umathsubsupshiftdown	_	SubscriptShiftDown	sub2
\Umathsubtopmax	_	SubscriptTopMax	(abs(math_x_height * 4) / 5)
\Umathsubsupvgap	_	SubSuperscriptGapMin	4*default_rule_thickness
\Umathsupbottommin	_	SuperscriptBottomMin	(abs(math_x_height) / 4)

\Umathsupshiftdrop	_	SuperscriptBaselineDropMax	sup_drop
\Umathsupshiftup	D	SuperscriptShiftUp	sup1
п	T, S, SS,	SuperscriptShiftUp	sup2
п	D', T', S', SS'	SuperscriptShiftUpCramped	sup3
\Umathsupsubbottommax	_	SuperscriptBottomMaxWithSubscript	(abs(math_x_height * 4) / 5)
\Umathunderbarkern	_	UnderbarExtraDescender	default_rule_thickness
\Umathunderbarrule	_	UnderbarRuleThickness	default_rule_thickness
\Umathunderbarvgap	_	UnderbarVerticalGap	3*default_rule_thickness
\Umathconnectoroverlapmin	_	MinConnectorOverlap	$0^{5}$

Note 1: OpenType fonts set \Umathfractiondelsize, \Umathlimitabovekern, \Umathlimitbelowkern to zero and set \Umathquad to the font size of the used font, because these are not supported in the MATH table,

Note 2: tfm fonts do not set  $\Umathradicalrule$  because  $T_EX82$  uses the height of the radical instead. When this parameter is indeed not set when Lua $T_EX$  has to typeset a radical, a backward compatibility mode will kick in that assumes that an oldstyle  $T_EX$  font is used. Also, they do not set  $\Umathradicaldegreebefore$ ,  $\Umathradicaldegreeafter$ , and  $\Umathradicaldegreeraise$ . These are then automatically initialized to 5/18quad, -10/18quad, and 60.

Note 3: If tfm fonts are used, then the \Umathradicalvgap is not set until the first time LuaTEX has to typeset a formula because this needs parameters from both family2 and family3. This provides a partial backward compatibility with TEX82, but that compatibility is only partial: once the \Umathradicalv-gap is set, it will not be recalculated any more.

Note 4: (also if tfm fonts are used) A similar situation arises wrt. \Umathspaceafterscript: it is not set until the first time LuaTeX has to typeset a formula. This provides some backward compatibility with TeX82. But once the \Umathspaceafterscript is set, \scriptspace will never be looked at again.

Note 5: Tfm fonts set \Umathconnectoroverlapmin to zero because TEX82 always stacks extensibles without any overlap.

Note 6: The \Umathoperatorsize is only used in \displaystyle, and is only set in OpenType fonts. In tfm font mode, it is artificially set to one scaled point more than the initial attempt's size, so that always the 'first next' will be tried, just like in TEX82.

Note 7: The \Umathradicaldegreeraise is a special case because it is the only parameter that is expressed in a percentage instead of as a number of scaled points.

## 5.5 Math spacing setting

Besides the parameters mentioned in the previous sections, there are also 64 new primitives to control the math spacing table (as explained in Chapter 18 of the TEXbook). The primitive names are a simple matter of combining two math atom types, but for completeness' sake, here is the whole list:

\Umathbinordspacing	\Umathbinopenspacing
\Umathbinopspacing	\Umathbinclosespacing
\Umathbinbinspacing	\Umathbinpunctspacing
\Umathbinrelspacing	\Umathbininnerspacing

\Umathrelordspacing \Umathrelopspacing \Umathrelbinspacing \Umathrelrelspacing \Umathrelopenspacing \Umathrelclosespacing \Umathrelpunctspacing \Umathrelinnerspacing \Umathopenordspacing \Umathopenopspacing \Umathopenbinspacing \Umathopenrelspacing \Umathopenopenspacing \Umathopenclosespacing \Umathopenpunctspacing \Umathopeninnerspacing \Umathcloseordspacing \Umathcloseopspacing \Umathclosebinspacing \Umathcloserelspacing \Umathcloseopenspacing

\Umathcloseclosespacing \Umathclosepunctspacing \Umathcloseinnerspacing \Umathpunctordspacing \Umathpunctopspacing \Umathpunctbinspacing \Umathpunctrelspacing \Umathpunctopenspacing \Umathpunctclosespacing \Umathpunctpunctspacing \Umathpunctinnerspacing \Umathinnerordspacing \Umathinneropspacing \Umathinnerbinspacing \Umathinnerrelspacing \Umathinneropenspacing \Umathinnerclosespacing \Umathinnerpunctspacing \Umathinnerinnerspacing

These parameters are of type \muskip, so setting a parameter can be done like this:

#### \Umathopordspacing\displaystyle=4mu plus 2mu

They are all initialized by initex to the values mentioned in the table in Chapter 18 of the TEXbook.

Note 1: for ease of use as well as for backward compatibility, \thinmuskip, \medmuskip and \thick-muskip are treated especially. In their case a pointer to the corresponding internal parameter is saved, not the actual \muskip value. This means that any later changes to one of these three parameters will be taken into account.

Note 2: Careful readers will realise that there are also primitives for the items marked \* in the TEXbook. These will not actually be used as those combinations of atoms cannot actually happen, but it seemed better not to break orthogonality. They are initialized to zero.

### 5.5.1 Math accent handling

LuaTEX supports both top accents and bottom accents in math mode. For bottom accents, there is the new primitive  $\U$ mathbotaccent. If you want to set both top and bottom accents on a single item, there is  $\U$ mathaccents.

If a math top accent has to be placed and the accentee is a character and has a non-zero top\_accent value, then this value will be used to place the accent instead of the \skewchar kern used by TFX82.

The top\_accent value represents a vertical line somewhere in the accentee. The accent will be shifted horizontally such that its own top\_accent line coincides with the one from the accentee. If

the top\_accent value of the accent is zero, then half the width of the accent followed by its italic correction is used instead.

The vertical placement of a top accent depends on the x\_height of the font of the accentee (as explained in the TEXbook), but if value that turns out to be zero and the font had a MathConstants table, then AccentBaseHeight is used instead.

If a math bottom accent has to be placed, the bot\_accent value is checked instead of top\_accent. Because bottom accents do not exist in TFX82, the \skewchar kern is ignored.

The vertical placement of a bottom accent is straight below the accentee, no correction takes place.

LuaTEX has horizontal extensibles, and when present, these will be used by the accent commands.

#### 5.5.2 Math root extension

The new primitive \Uroot allows the construction of a radical noad including a degree field. Its syntax is an extension of \Uradical:

The placement of the degree is controlled by the math parameters \Umathradicaldegreebefore, \Umathradicaldegreeafter, and \Umathradicaldegreeraise. The degree will be typeset in \scriptscriptstyle.

### 5.5.3 Scripts on horizontally extensible items like arrows

The new primitives \Uunderdelimiter and \Uoverdelimiter allow the placement of a subscript or superscript on an automatically extensible item. The vertical placements are controlled by \Umathunderdelimiterbgap, \Umathunderdelimitervgap, \Umathoverdelimiterbgap, and \Umathoverdelimitervgap in a similar way as limit placements on large operators. The superscript in \Uoverdelimiter is typeset in a suitable scripted style, the subscript in \Uunderdelimiter is cramped as well.

### 5.6 Extensible delimiters

LuaTEX internally uses a structure that supports OpenType 'MathVariants' as well as tfm 'extensible recipes'.

## 5.7 Other Math changes

#### 5.7.1 Allowed math commands in non-math modes

The commands \mathchar, \omathchar, and \Umathchar and control sequences that are the result of \mathchardef, \omathchardef, or \Umathchardef are also acceptable in the horizontal and vertical modes. In those cases, the \textfont from the requested math family is used.

### 5.8 Math todo

The following items are all still todo before LuaTEX 0.40.

- Pre-scripts.
- Multi-story stacks.
- Support for extensible big operators.
- Make a \mathstyle parameter that can be queried during math list parsing (this implies a new primitive to deal with {.. \over ..} and {.. \atop ..}).
- Staggered kerning (the math\_kern array in OpenType).
- Allow setting of the math parameters directly from Lua.
- Implement \Uoverunderdelimiters (?).
- Flattened accents for high characters (?).
- Better control over the spacing around displays and handling of equation numbers.
- Support for multi-line displays using MathML style alignment points.
- The eight 'normal' noads will be merged into a single node id with subtypes.

# 6 Languages and characters, fonts and glyphs

LuaTEX's internal handling of the characters and glyphs that eventually become typeset is quite different from the way TEX82 handles those same objects. The easiest way to explain the difference is to focus on unrestricted horizontal mode (i. e. paragraphs) and hyphenation first. Later on, it will be easy to deal with the differences that occur in horizontal and math modes.

In TEX82, the characters you type are converted into char\_node records when they are encountered by the main control loop. TEX attaches and processes the font information while creating those records, so that the resulting 'horizontal list' contains the final forms of ligatures and implicit kerning. This packaging is needed because we may want to get the effective width of for instance a horizontal box.

When it becomes necessary to hyphenate words in a paragraph, TEX converts (one word at time) the char\_node records into a string array by replacing ligatures with their components and ignoring the kerning. Then it runs the hyphenation algorithm on this string, and converts the hyphenated result back into a 'horizontal list' that is consecutively spliced back into the paragraph stream. Keep in mind that the paragraph may contain unboxed horizontal material, which then already contains ligatures and kerns and the words therein are part of the hyphenation process.

The char\_node records are somewhat misnamed, as they are glyph positions in specific fonts, and therefore not really 'characters' in the linguistic sense. There is no language information inside the char\_node records. Instead, language information is passed along using language whatsit records inside the horizontal list.

In LuaT<sub>E</sub>X, the situation is quite different. The characters you type are always converted into glyph\_node records with a special subtype to identify them as being intended as linguistic characters. LuaT<sub>E</sub>X stores the needed language information in those records, but does not do any font-related processing at the time of node creation. It only stores the index of the font.

When it becomes necessary to typeset a paragraph, LuaTEX first inserts all hyphenation points right into the whole node list. Next, it processes all the font information in the whole list (creating ligatures and adjusting kerning), and finally it adjusts all the subtype identifiers so that the records are 'glyph nodes' from now on.

That was the broad overview. The rest of this chapter will deal with the minutiae of the new process.

## 6.1 Characters and glyphs

TEX82 (including pdfTEX) differentiated between char\_nodes and lig\_nodes. The former are simple items that contained nothing but a 'character' and a 'font' field, and they lived in the same memory as tokens did. The latter also contained a list of components, and a subtype indicating whether this ligature was the result of a word boundary, and it was stored in the same place as other nodes like boxes and kerns and glues.

In LuaTEX, these two types are merged into one, somewhat larger structure called a glyph\_node. Besides having the old character, font, and component fields, and the new special fields like 'attr' (see section 8.1.2.12), these nodes also contain:

- A subtype, split into four main types:
  - character, for characters to be hyphenated: the lowest bit (bit 0) is set to 1.
  - glyph, for specific font glyphs: the lowest bit (bit 0) is not set.
  - ligature, for ligatures (bit 1 is set)
  - ghost, for 'qhost objects' (bit 2 is set)

The latter two make further use of two extra fields (bits 3 and 4):

- left, for ligatures created from a left word boundary and for ghosts created from \leftghost
- right, for ligatures created from a right word boundary and for ghosts created from \rightghost

For ligatures, both bits can be set at the same time (in case of a single-glyph word).

• glyph\_nodes of type 'character' also contain language data, split into four items that were current when the node was created: the \setlanguage (15 bits), \lefthyphenmin (8 bits), \righthyphenmin (8 bits), and \uchyph (1 bit).

Incidentally, LuaTFX allows 32768 separate languages, and words can be 256 characters long.

Because the \uchyph value is saved in the actual nodes, its handling is subtly different from TEX82: changes to \uchyph become effective immediately, not at the end of the current partial paragraph.

Typeset boxes now always have their language information embedded in the nodes themselves, so there is no longer a possible dependency on the surrounding language settings. In TEX82, a mid-paragraph statement like \unhbox0 would process the box using the current paragraph language unless there was a \setlanguage issued inside the box. In LuaTEX, all language variables are already frozen.

## 6.2 The main control loop

In LuaTEX's main loop, almost all input characters that are to be typeset are converted into glyph\_node records with subtype 'character', but there are a few small exceptions.

First, the \accent primitives creates nodes with subtype 'glyph' instead of 'character': one for the actual accent and one for the accentee. The primary reason for this is that \accent in TEX82 is explicitly dependent on the current font encoding, so it would not make much sense to attach a new meaning to the primitive's name, as that would invalidate many old documents and macro packages. A secondary reason is that in TEX82, \accent prohibits hyphenation of the current word. Since in LuaTEX hyphenation only takes place on 'character' nodes, it is possible to achieve the same effect.

This change of meaning did happen with \char, that now generates 'character' nodes, consistent with its changed meaning in X¬TEX. The changed status of \char is not yet finalized, but if it stays as it is now, a new primitive \glyph should be added to directly insert a font glyph id.

Second, all the results of processing in math mode eventually become nodes with 'glyph' subtypes.

Third, the Aleph-derived commands \leftghost and \rightghost create nodes of a third subtype: 'ghost'. These nodes are ignored completely by all further processing until the stage where inter-glyph kerning is added.

Fourth, automatic discretionaries are handled differently. TEX82 inserts an empty discretionary after sensing an input character that matches the \hyphenchar in the current font. This test is wrong, in our

opinion: whether or not hyphenation takes place should not depend on the current font, it is a language property.

In LuaT<sub>E</sub>X, it works like this: if LuaT<sub>E</sub>X senses a string of input characters that matches the value of the new integer parameter \exhyphenchar, it will insert an explicit discretionary after that series of nodes. Initex sets the \exhyphenchar=`\-. Incidentally, this is a global parameter instead of a language-specific one because it may be useful to change the value depending on the document structure instead of the text language.

The only use LuaTEX has for \hyphenchar is at the check whether a word should be considered for hyphenation at all. If the \hyphenchar of the font attached to the first character node in a word is negative, then hyphenation of that word is abandoned immediately. This behaviour is added for backward compatibility only, and the use of \hyphenchar=-1 as a means of preventing hyphenation should not be used in new LuaTEX documents.

Fifth, \setlanguage no longer creates whatsits. The meaning of \setlanguage is changed so that it is now an integer parameter like all others. That integer parameter is used in \glyph\_node creation to add language information to the glyph nodes. In conjunction, the \language primitive is extended so that it always also updates the value of \setlanguage.

Sixth, the \noboundary command (this command prohibits word boundary processing where that would normally take place) now does create whatsits. These whatsits are needed because the exact place of the \noboundary command in the input stream has to be retained until after the ligature and font processing stages.

Finally, there is no longer a main\_loop label in the code. Remember that TEX82 did quite a lot of processing while adding char\_nodes to the horizontal list? For speed reasons, it handled that processing code outside of the 'main control' loop, and only the first character of any 'word' was handled by that 'main control' loop. In LuaTEX, there is no longer a need for that (all hard work is done later), and the (now very small) bits of character-handling code have been moved back inline. When \tracingcommands is on, this is visible because the full word is reported, instead of just the initial character.

## 6.3 Loading patterns and exceptions

The hyphenation algorithm in LuaTEX is quite different from the one in TEX82, although it uses essentially the same user input.

After expansion, the argument for \patterns has to be proper UTF-8, no \char or \chardef-ed commands are allowed. (The current implementation is even more strict, and will reject all non-Unicode characters, but that will be changed in the future. For now, the generated errors are a valuable tool in discovering font-encoding specific pattern files)

Likewise, the expanded argument for \hyphenation also has to be proper UTF-8, but here a tiny little bit of extra syntax is provided:

- 1. three sets of arguments in curly braces ({}{}}) indicates a desired complex discretionary, with arguments as in \discretionary's command in normal document input.
- 2. indicates a desired simple discretionary, cf. \- and \discretionary- in normal document input.

- 3. Internal command names are ignored. This rule is provided especially for \discretionary, but it also helps to deal with \relax commands that may sneak in.
- 4. = indicates a hyphen in the document input (but that is only useful in documents where \exhyphenchar is not equal to the hyphen).

The expanded argument is first converted back to a space-separated string while dropping the internal command names. This string is then converted into a dictionary by a routine that creates key—value pairs by converting the other listed items. It is important to note that the keys in an exception dictionary can always be generated from the values. Here are a few examples:

value implied key (input) effect ta-ble table ta\-ble (= ta\discretionary  $\{-\}\{\}\}$ ble) ba $\{k-\}\{\}\{c\}$ ken backen ba\discretionary  $\{k-\}\{\}\{c\}$ ken

The resultant patterns and exception dictionary will be stored under the language code that is the present value of \language.

In the last line of the table, you see there is no \discretionary command in the value: the command is optional in the TEX-based input syntax. The underlying reason for that is that it is conceivable that a whole dictionary of words is stored as a plain text file and loaded into LuaTEX using one of the functions in the Lua lang library. This loading method is quite a bit faster than going through the TEX language primitives, but some (most?) of that speed gain would be lost if it had to interpret command sequences while doing so.

The motivation behind the  $\varepsilon$ -TEX extension \savinghyphcodes was that hyphenation heavily depended on font encodings. This is no longer true in LuaTEX, and the corresponding primitive is ignored pending complete removal. The future semantics of \uppercase and \lowercase are still under consideration, no changes have taken place yet.

## 6.4 Applying hyphenation

The internal structures LuaTEX uses for the insertion of discretionaries in words is very different from the ones in TEX82, and that means there are some noticable differences in handling as well.

First and foremost, there is no 'compressed trie' involved in hyphenation. The algorithm still reads patgen-generated pattern files, but LuaTEX uses a finite state hash to match the patterns against the word to be hyphenated. This algorithm is based on the 'libhnj' library used by OpenOffice, which in turn is inspired by TEX. The memory allocation for this new implementation is completely dynamic, so the web2c setting for trie\_size is ignored.

Differences between LuaTFX and TFX82 that are a direct result of that:

- LuaTFX happily hyphenates the full Unicode character range.
- Pattern and exception dictionary size is limited by the available memory only, all allocations are done dynamically. The trie-related settings in texmf.cnf are ignored.

- Because there is no 'trie preparation' stage, language patterns never become frozen. This means that
  the primitive \patterns (and its Lua counterpart lang.patterns) can be used at any time, not
  only in initex.
- Only the string representation of \patterns and \hyphenation is stored in the format file. At format load time, they are simply re-evaluated. It follows that there is no real reason to preload languages in the format file. In fact, it is usually not a good idea to do so. It is much smarter to load patterns no sooner than the first time they are actually needed.
- LuaTEX uses the language-specific variables \prehyphenchar and \posthyphenchar in the creation of implicit discretionaries, instead of TEX82's \hyphenchar, and the values of the language-specific variables \preexhyphenchar and \postexhyphenchar for explicit discretionaries (instead of TEX82's empty discretionary).

Previously, there were problems with changing the node attributes mid-word, but that problem is now solved, as nodes in a word are not converted to and from a string any more (this was required by the old hyphenation code), they are edited in place. Inserted characters and ligatures inherit their attributes from the nearest glyph node item (usually the preceding one, but the following one for the items inserted at the left-hand side of a word).

Word boundaries are no longer implied by font switches, but by language switches. One word can have two separate fonts and still be hyphenated correctly (but it can not have two different languages, the \setlanguage command forces a word boundary).

All languages start out with \prehyphenchar=`\-, \posthyphenchar=0, \preexhyphenchar=0 and \postexhyphenchar=0. When you assign the values of one of these four parameters, you are actually changing the settings for the current \language, this behavior is compatible with \patterns and \hyphenation.

LuaTFX also hyphenates the first word in a paragraph.

Words can be up to 256 characters long (up from 64 in TEX82). Longer words generate an error right now, but eventually either the limitation will be removed or perhaps it will become possible to silently ignore the excess characters (this is what happens in TEX82, but there the behaviour cannot be controlled).

If you are using the Lua function lang.hyphenate, you should be aware that this function expects to receive a list of 'character' nodes. It will not operate properly in the presence of 'glyph', 'ligature', or 'ghost' nodes, nor does it know how to deal with kerning. In the near future, it will be able to skip over 'ghost' nodes, and we may add a less fuzzy function you can call as well.

The hyphenation exception dictionary is maintained as key-value hash, and that is also dynamic, so the hyph\_size setting is not used either.

A technical paper detailing the new algorithm will be released as a separate document.

# 6.5 Applying ligatures and kerning

After all possible hyphenation points have been inserted in the list, LuaTEX will process the list to convert the 'character' nodes into 'glyph' and 'ligature' nodes. This is actually done in two stages: first all ligatures are processed, then all kerning information is applied to the result list. But those two

stages are somewhat dependent on each other: If the used font makes it possible to do so, the ligaturing stage adds virtual 'character' nodes to the word boundaries in the list. While doing so, it removes and interprets noboundary nodes. The kerning stage deletes those word boundary items after it is done with them, and it does the same for 'ghost' nodes. Finally, at the end of the kerning stage, all remaining 'character' nodes are converted to 'glyph' nodes.

This work separation is worth mentioning because, if you overrule from Lua only one of the two callbacks related to font handling, then you have to make sure you perform the tasks normally done by LuaTEX itself in order to make sure that the other, non-overruled, routine continues to function properly.

Work in this area is not yet complete, but most of the possible cases are handled by our rewritten ligaturing engine. We are working hard to make sure all of the possible inputs will become supported soon.

For example, take the word office, hyphenated of-fice, using a 'normal' font with all the f-i ligatures:

```
Initial: \{o\}\{f\}\{i\}\{c\}\{e\}
```

After hyphenation:  $\{0\}\{\{-\}, \{\}, \{\}\}\{i\}\{c\}\{e\}\}$ First ligature stage:  $\{0\}\{\{f\}\{-\}, \{f\}, \{ff\}\}\{i\}\{c\}\{e\}\}$ Final result:  $\{0\}\{\{f\}\{-\}, \{fi\}, \{ffi\}\}\{c\}\{e\}$ 

That's bad enough, but if there was a hyphenation point between the f and the i: of-f-ice, the final result should be:

```
{o}{{f}{-},
    {{f}}{-},
    {i},
    {fi}},
    {fff}{-},
    {fff}{-},
    {fff}{-},
    {ij},
    {ffi}}}
```

with discretionaries in the post-break text as well as in the replacement text of the top-level discretionary that resulted from the first hyphenation point. And this is only a simple case.

## 6.6 Breaking paragraphs into lines

This code is still almost unchanged, but because of the above-mentioned changes with respect to discretionaries and ligatures, line breaking will potentially be different from traditional TEX. The actual line breaking code is still based on the TEX82 algorithms, and it does not expect there to be discretionaries inside of discretionaries.

But that situation is now fairly common in LuaT<sub>E</sub>X, due to the changes to the ligaturing mechanism. And also, the LuaT<sub>E</sub>X discretionary nodes are implemented slightly different from the T<sub>E</sub>X82 nodes: the no\_break text is now embedded inside the disc node, where previously these nodes kept their place in the horizontal list (the discretionary node contained a counter indicating how many nodes to skip).

The combined effect of these two differences is that LuaTEX does not always use all of the potential breakpoints in a paragraph, especially when fonts with many ligatures are used.

## **7** Font structure

All TEX fonts are represented to Lua code as tables, and internally as C structures. All keys in the table below are saved in the internal font structure if they are present in the table returned by the define\_font callback, or if they result from the normal tfm/vf reading routines if there is no define\_font callback defined.

The column 'from vf' means that this key will be created by the font.read\_vf() routine, 'from tfm' means that the key will be created by the font.read\_tfm() routine, and 'used' means whether or not the LuaTEX engine itself will do something with the key.

The top-level keys in the table are as follows:

key	from vf	from tfm	used	value type	description
name	yes	yes	yes	string	metric (file) name
area	no	yes	yes	string	(directory) location, typically empty
used	no	yes	yes	boolean	used already? (initial: false)
characters	yes	yes	yes	table	the defined glyphs of this font
checksum	yes	yes	no	number	default: 0
designsize	no	yes	yes	number	expected size (default: $655360 == 10pt$ )
direction	no	yes	yes	number	
					default: 0 (LTR)
encodingbytes	no	no	yes	number	default: depends on format
encodingname	no	no	yes	string	encoding name
fonts	yes	no	yes	table	locally used fonts
fullname	no	no	yes	string	actual (PostScript) name
header	yes	no	no	string	header comments, if any
hyphenchar	no	no	yes	number	default: TeX's \hyphenchar
parameters	no	yes	yes	hash	default: 7 parameters, all zero
size	no	yes	yes	number	loaded (at) size. (default: same as de-
					signsize)
skewchar	no	no	yes	number	default: TeX's \skewchar
type	yes	no	yes	string	basic type of this font
format	no	no	yes	string	disk format type
embedding	no	no	yes	string	pdf inclusion
filename	no	no	yes	string	disk file name
tounicode	no	yes	yes	number	if 1, LuaT <sub>E</sub> X assumes per-glyph touni-
					code entries are present in the font
stretch	no	no	yes	number	the 'stretch' value from \pdffontex-
					pand
shrink	no	no	yes	number	the 'shrink' value from \pdffontex-
					pand
step	no	no	yes	number	the 'step' value from \pdffontexpand

auto_expand	no	no	yes	boolean	the 'autoexpand' keyword from \pdf-
					fontexpand
expansion_factor	no	no	no	number	the actual expansion factor of an ex-
					panded font
attributes	no	no	yes	string	the \pdffontattr

The key name is always required. The keys stretch, shrink, step and optionally auto\_expand only have meaning when used together: they can be used to replace a post-loading \pdffontexpand command. The expansion\_factor is value that can be present inside a font in font.fonts. It is the actual expansion factor (a value between -shrink and stretch, with step step) of a font that was automatically generated by the font expansion algorithm. The key attributes can be used to replace \pdffontattr. The key used is set by the engine when a font is actively in use, this makes sure that the font's definition is written to the output file (dvi or pdf). The tfm reader sets it to false. The direction is a number signalling the 'normal' direction for this font. There are sixteen possibilities:

number	meaning	number	meaning
0	LT	8	TT
1	LL	9	TL
2	LB	10	TB
3	LR	11	TR
4	RT	12	BT
5	RL	13	BL
6	RB	14	BB
7	RR	15	BR

These are Omega-style direction abbreviations: the first character indicates the 'first' edge of the character glyphs (the edge that is seen first in the writing direction), the second the 'top' side.

The parameters is a hash with mixed key types. There are seven possible string keys, as well as a number of integer indices (these start from 8 up). The seven strings are actually used instead of the bottom seven indices, because that gives a nicer user interface.

The names and their internal remapping are:

name	internal remapped number
slant	1
space	2
space_stretch	3
space_shrink	4
x_height	5
quad	6
extra_space	7

The keys type, format, embedding, fullname and filename are used to embed OpenType fonts in the result pdf.

The characters table is a list of character hashes indexed by an integer number. The number is the 'internal code' TFX knows this character by.

Two very special string indexes can be used also: left\_boundary is a virtual character whose ligatures and kerns are used to handle word boundary processing. right\_boundary is similar but not actually used for anything (yet!).

Other index keys are ignored.

Each character hash itself is a hash. For example, here is the character 'f' (decimal 102) in the font cmr10 at 10 points:

```
[102] = {
    ['width'] = 200250,
    ['height'] = 455111,
    ['depth'] = 0,
    ['italic'] = 50973,
    ['kerns'] = {
        [63] = 50973,
        [93] = 50973,
        [39] = 50973,
        [33] = 50973,
        [41] = 50973
    },
    ['ligatures'] = {
        [102] = {
             ['char'] = 11,
             ['type'] = 0
        },
        [108] = {
             ['char'] = 13,
             ['type'] = 0
        },
        [105] = {
             ['char'] = 12,
             ['type'] = 0
        }
    }
}
```

Of course a more compact is also possible, but keep in mind that reserved words cannot be used compact and in  $LuaT_EX$  we often have a type key.

```
[102] = {
    ...
    ligatures = {
        [102] = {
            char = 11,
            ['type'] = 0
```

```
},
...
}
```

The following top-level keys can be present inside a character hash:

key	from vf	from tfm	used	value type	description
width	yes	yes	yes	number	character's width, in sp (default 0)
height	no	yes	yes	number	character's height, in sp (default 0)
depth	no	yes	yes	number	character's depth, in sp (default 0)
italic	no	yes	yes	number	character's italic correction, in sp (default zero)
top_accent	no	no	maybe	number	character's top accent alignment place, in sp (default zero)
bot_accent	no	no	maybe	number	character's bottom accent alignment place, in sp (default zero)
left_protruding	no	no	maybe	number	character's \lpcode
right_protruding	no	no	maybe	number	character's \rpcode
expansion_factor	no	no	maybe	number	character's \efcode
tounicode	no	no	maybe	string	character's Unicode equivalent(s), in UTF-16BE hexadecimal format
next	no	yes	yes	number	the 'next larger' character index
extensible	no	yes	yes	table	the constituent parts of an extensible recipe
vert_variants	no	no	yes	table	constituent parts of a vertical variant set
horiz_variants	no	no	yes	table	constituent parts of a horizontal variant set
kerns	no	yes	yes	table	kerning information
ligatures	no	yes	yes	table	ligaturing information
commands	yes	no	yes	array	virtual font commands
name	no	no	no	string	the character (PostScript) name
index	no	no	yes	number	the (OpenType or TrueType) font glyph index
used	no	yes	yes	boolean	typeset already (default: false)?

The values of top\_accent and bot\_accent are used only for math accent placement, see the 95math chapter in this manual for details.

The values of left\_protruding and right\_protruding are used only when \pdfprotrudechars is non-zero.

Whether or not expansion\_factor is used depends on the font's global expansion settings, as well as on the value of \pdfadjustspacing.

The usage of tounicode is this: if this font specifies a tounicode=1 at the top level, then LuaTEX will construct a /ToUnicode entry for the pdf font (or font subset) based on the character-level tounicode strings, where they are available. If a character does not have a sensible Unicode equivalent, do not provide a string either (no empty strings).

If the font-level tounicode is not set, then LuaTEX will build up /ToUnicode based on the TEX code points you used, and any character-level tounicodes will be ignored. At the moment, the string format is exactly the format that is expected by Adobe CMap files (utf-16BE in hexadecimal encoding), minus the enclosing angle brackets. This may change in the future. Small example: the tounicode for a fi ligature would be 00660069.

The presence of extensible will overrule next, if that is also present. It in in turn can be overruled by vert\_variants.

The extensible table is very simple:

key	type	description
top	number	'top' character index
mid	number	'middle' character index
bot	number	'bottom' character index
rep	number	'repeatable' character index

The horiz\_variants and vert\_variants are arrays of components. Each of those components is itself a hash of up to five keys:

key	type	explanation
component	number	The character index (note that this is an encoding number, not a name).
extender	number	One (1) if this part is repeatable, zero (0) otherwise.
start	number	Maximum overlap at the starting side (in scaled points).
end	number	Maximum overlap at the ending side (in scaled points).
advance	number	Total advance width of this item (can be zero or missing, then the natural size
		of the glyph for character component is used).

The kerns table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right\_boundary), with the values the kerning to be applied, in scaled points.

The ligatures table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right\_boundary), with the values being yet another small hash, with two fields:

```
key type description
type number the type of this ligature command, default 0
char number the character index of the resultant ligature
```

The **char** field in a ligature is required.

The type field inside a ligature is the numerical or string value of one of the eight possible ligature types supported by TEX. When TEX inserts a new ligature, it puts the new glyph in the middle of the

left and right glyphs. The original left and right glyphs can optionally be retained, and when at least one of them is kept, it is also possible to move the new 'insertion point' forward one or two places. The glyph that ends up to the right of the insertion point will become the next 'left'.

textual (Knuth)	number	string	result
l + r =: n	0	=:	n
l + r =:   n	1	=:	nr
l + r =: n	2	=:	ln
l + r =  n	3	=:	lnr
l + r =:  > n	5	=:  >	n r
l + r =:> n	6	=:>	l∣n
l + r = > n	7	=: >	l nr
l + r = > n	11	=: >>	ln r

The default value is 0, and can be left out. That signifies a 'normal' ligature where the ligature replaces both original glyphs. In this table the | indicates the final insertion point.

The commands array is explained below.

### 7.1 Real fonts

Whether or not a TEX font is a 'real' font that should be written to the pdf document is decided by the type value in the top-level font structure. If the value is real, then this is a proper font, and the inclusion mechanism will attempt to add the needed font object definitions to the pdf.

Values for type:

value	description
real	this is a base font
virtual	this is a virtual font

The actions to be taken depend on a number of different variables:

- Whether the used font fits in an 8-bit encoding scheme or not
- The type of the disk font file
- The level of embedding requested

A font that uses anything other than an 8-bit encoding vector has to be written to the pdf in a different way.

The rule is: if the font table has encodingbytes set to 2, then this is a wide font, in all other cases it isn't. The value 2 is the default for OpenType and TrueType fonts loaded via Lua. For Type1 fonts, you have to set encodingbytes to 2 explicitly. For pk bitmap fonts, wide font encoding is not supported at all.

If no special care is needed, LuaTEX currently falls back to the mapfile-based solution used by pdfTEX and dvips. This behaviour will be removed in the future, when the existing code becomes integrated in the new subsystem.

But if this is a 'wide' font, then the new subsystem kicks in, and some extra fields have to be present in the font structure. In this case, LuaTFX does not use a map file at all.

The extra fields are: format, embedding, fullname, cidinfo (as explained above), filename, and the index key in the separate characters.

Values for format are:

value description

type1 this is a PostScript Type1 font
type3 this is a bitmapped (pk) font

truetype this is a TrueType or TrueType-based OpenType font

opentype this is a PostScript-based OpenType font

(type3 fonts are provided for backward compatibility only, and do not support the new wide encoding options.)

Values for embedding are:

value description

no don't embed the font at all

subset include and atttempt to subset the font

full include this font in its entirety

It is not possible to artificially modify the transformation matrix for the font at the moment.

The other fields are used as follows: The fullname will be the PostScript/pdf font name. The cidinfo will be used as the character set (the CID /Ordering and /Registry keys). The filename points to the actual font file. If you include the full path in the filename or if the file is in the local directory, LuaTeX will run a little bit more efficient because it will not have to re-run the find\_xxx\_file callback in that case.

Be careful: when mixing old and new fonts in one document, it is possible to create PostScript name clashes that can result in printing errors. When this happens, you have to change the fullname of the font.

Typeset strings are written out in a wide format using 2 bytes per glyph, using the index key in the character information as value. The overall effect is like having an encoding based on numbers instead of traditional (PostScript) name-based reencoding. The way to get the correct index numbers for Type1 fonts is by loading the font via fontforge.open; use the table indices as index fields.

This type of reencoding means that there is no longer a clear connection between the text in your input file and the strings in the output pdf file. Dealing with this is high on the agenda.

### 7.2 Virtual fonts

You have to take the following steps if you want LuaTEX to treat the returned table from define\_font as a virtual font:

- Set the top-level key type to virtual.
- Make sure there is at least one valid entry in fonts (see below).
- Give a commands array to every character (see below).

The presence of the toplevel type key with the specific value virtual will trigger handling of the rest of the special virtual font fields in the table, but the mere existence of 'type' is enough to prevent LuaTEX from looking for a virtual font on its own.

Therefore, this also works 'in reverse': if you are absolutely certain that a font is not a virtual font, assigning the value base or real to type will inhibit LuaTEX from looking for a virtual font file, thereby saving you a disk search.

The fonts is another Lua array. The values are one- or two-key hashes themselves, each entry indicating one of the base fonts in a virtual font. In case your font is referring to itself, you can use the font.nextid() function which returns the index of the next to be defined font which is probably the currently defined one.

An example makes this easy to understand

says that the first referenced font (index 1) in this virtual font is ptrmr8a loaded at 10pt, and the second is psyr loaded at a little over 9pt. The third one is previously defined font that is known to LuaTEX as fontid '38'.

The array index numbers are used by the character command definitions that are part of each character.

The commands array is a hash where each item is another small array, with the first entry representing a command and the extra items being the parameters to that command. The allowed commands and their arguments are:

command name	arguments	arg type	description
font	1	number	select a new font from the local fonts table
char	1	number	typeset this character number from the current font, and move
			right by the character's width
node	1	node	output this node (list), and move right by the width of this
			list
slot	2	number	a shortcut for the combination of a font and char command
push	0		save current position

```
0
                                        do nothing
nop
                0
                                        pop position
pop
                2
rule
                             2 numbers
                                        output a rule ht * wd, and move right.
                1
                             number
                                        move down on the page
down
                1
                             number
                                        move right on the page
right
special
                1
                             string
                                        output a \special command
                1
                                        output an image (the argument can be either an <image>
image
                             image
                                        variable or an image_spec table)
                                        the arguments of this command are ignored
comment
                any
                             any
```

Here is a rather elaborate glyph commands example:

```
commands = {
  {'push'},
                                 -- remember where we are
  {'right', 5000},
                                 -- move right about 0.08pt
  {'font', 3},
                                 -- select the fonts[3] entry
  {'char', 97},
                                 -- place character 97 (ASCII 'a')
  {'pop'},
                                 -- go all the way back
  {'down', -200000},
                                 -- move upwards by about 3pt
  {'special', 'pdf: 1 0 0 rg'}
                                 -- switch to red color
  {'rule', 500000, 20000}
                                 -- draw a bar
  {'special','pdf: 0 g'}
                                 -- back to black
}
```

The default value for font is always 1 at the start of the commands array. Therefore, if the virtual font is essentially only a re-encoding, then you do usually not have create an explicit 'font' command in the array.

Rules inside of commands arrays are built up using only two dimensions: they do not have depth. For correct vertical placement, an extra down command may be needed.

Regardless of the amount of movement you create within the commands, the output pointer will always move by exactly the width that was given in the width key of the character hash. Any movements that take place inside the commands array are ignored on the upper level.

#### 7.2.1 Artificial fonts

Even in a 'real' font, there can be virtual characters. When LuaTEX encounters a commands field inside a character when it becomes time to typeset the character, it will interpret the commands, just like for a true virtual character. In this case, if you have created no 'fonts' array, then the default (and only) 'base' font is taken to be the current font itself. In practice, this means that you can create virtual duplicates of existing characters which is useful if you want to create composite characters.

Note: this feature does not work the other way around. There can not be 'real' characters in a virtual font! You cannot use this technique for font re-encoding either; you need a truly virtual font for that (because characters that are already present cannot be altered).

### 7.2.2 Example virtual font

Finally, here is a plain T<sub>E</sub>X input file with a virtual font demonstration:

```
\directlua {
  callback.register('define_font',
    function (name, size)
      if name == 'cmr10-red' then
        f = font.read tfm('cmr10',size)
        f.name = 'cmr10-red'
        f.type = 'virtual'
        f.fonts = {{ name = 'cmr10', size = size }}
        for i,v in pairs(f.characters) do
          if (string.char(i)):find('[tacohanshartmut]') then
             v.commands = {
               {'special','pdf: 1 0 0 rg'},
               {'char', i},
               {'special', 'pdf: 0 g'},
          else
             v.commands = {{'char',i}}
          end
        end
      else
        f = font.read_tfm(name, size)
      return f
    end
}
\font\myfont = cmr10-red at 10pt \myfont This is a line of text \par
```

\font\myfontx= cmr10 at 10pt \myfontx Here is another line of text \par

## 8 Nodes

## 8.1 LUA node representation

TEX's nodes are represented in Lua as userdata object with a variable set of fields. In the following syntax tables, such the type of such a userdata object is represented as  $\langle node \rangle$ .

The current return value of node.types() is: hlist (0), vlist (1), rule (2), ins (3), mark (4), adjust (5), disc (7), whatsit (8), math (9), glue (10), kern (11), penalty (12), unset (13), style (14), choice (15), ord (16), op (17), bin (18), rel (19), open (20), close (21), punct (22), inner (23), radical (24), fraction (25), under (26), over (27), accent (28), vcenter (29), fence (30), math\_char (31), sub\_box (32), sub\_mlist (33), math\_text\_char (34), delim (35), margin\_kern (36), glyph (37), align\_record (38), pseudo\_file (39), pseudo\_line (40), page\_insert (41), split\_insert (42), expr\_stack (43), nested\_list (44), span (45), attribute (46), glue\_spec (47), attribute\_list (48), action (49), temp (50), align\_stack (51), movement\_stack (52), if\_stack (53), unhyphenated (54), hyphenated (55), delta (56), passive (57), shape (58), fake (100), but as already mentioned, the math and alignment nodes in this list are not supported at the moment. The useful list is described in the next sections.

### 8.1.1 Auxiliary items

A few node-typed userdata objects do not occur in the 'normal' list of nodes, but can be pointed to from within that list. They are not quite the same as regular nodes, but it is easier for the library routines to treat them as if they were.

### 8.1.1.1 glue\_spec items

Skips are about the only type of data objects in traditional TEX that are not a simple value. The structure that represents the glue components of a skip is called a glue\_spec, and it has the following accessible fields:

key	type	explanation
width	number	
stretch	number	
stretch_order	number	
shrink	number	
shrink_order	number	

These objects are reference counted, so there is actually an extra field named ref\_count as well. This item type will likely disappear in the future, and the glue fields themselves will become part of the nodes referencing glue items.

#### 8.1.1.2 attribute\_list and attribute items

The newly introduced attribute registers are non-trivial, because the value that is attached to a node is essentially a sparse array of key-value pairs.

It is generally easiest to deal with attribute lists and attributes by using the dedicated functions in the node library, but for completeness, here is the low-level interface.

An attribute\_list item is used as a head pointer for a list of attribute items. It has only one user-visible field:

```
field type explanation
next <node> pointer to the first attribute
```

A normal node's attribute field will point to an item of type attribute\_list, and the next field in that item will point to the first defined 'attribute' item, whose next will point to the second 'attribute' item, etc.

Valid fields in attribute items:

field	type	explanation
next	<node></node>	pointer to the next attribute
number	number	the attribute type id
value	number	the attribute value

#### 8.1.1.3 action item

Valid fields: action\_type, named\_id, action\_id, file, new\_window, data, ref\_count These are a special kind of item that only appears inside pdf start link objects.

field	type	explanation
action_type	number	
action_id	number or string	
$named_id$	number	
file	string	
new_window	number	
data	string	
ref_count	number	

#### 8.1.2 Main text nodes

These are the nodes that comprise actual typesetting commands.

A few fields are present in all nodes regardless of their type, these are:

```
field type explanation
next <node> The next node in a list, or nil
```

```
id number The node's type (id) number subtype number The node subtype identifier
```

The subtype is sometimes just a stub entry. Not all nodes actually use the subtype, but this way you can be sure that all nodes accept it as a valid field name, and that is often handy in node list traversal. In the following tables next and id are not explicitly mentioned.

Besides these three fields, almost all nodes also have an attr field, and there is a also a field called prev. That last field is always present, but only initialized on explicit request: when the function node.slide() is called, it will set up the prev fields to be a backwards pointer in the argument node list.

#### 8.1.2.1 hlist nodes

Valid fields: attr, width, depth, height, dir, shift, glue\_order, glue\_sign, glue\_set, list

field	type	explanation
subtype	number	unused
attr	<node></node>	The head of the associated attribute list
width	number	
height	number	
depth	number	
shift	number	a displacement perpendicular to the character progression direction
glue_order	number	a number in the range 0–4, indicating the glue order
glue_set	number	the calculated glue ratio
glue_sign	number	
list	<node></node>	the body of this list
dir	string	the direction of this box. see 8.1.4.7

#### 8.1.2.2 vlist nodes

Valid fields: As for hlist, except that 'shift' is a displacement perpendicular to the line progression direction.

#### **8.1.2.3** rule nodes

Valid fields: attr, width, depth, height, dir

field	type	explanation
subtype	number	unused
attr	<node></node>	
width	number	the width of the rule; the special value $-1073741824$ is used for 'running' glue
		dimensions
height	number	the height of the rule (can be negative)

depth number the depth of the rule (can be negative)
dir string the direction of this rule. see 8.1.4.7

#### 8.1.2.4 ins nodes

Valid fields: attr, cost, depth, height, spec, list

field explanation type number subtype the insertion class attr <node> the penalty associated with this insert cost number height number depth number list <node> the body of this insert spec <node> a pointer to the \splittopskip glue spec

#### 8.1.2.5 mark nodes

Valid fields: attr, class, mark

field type explanation
subtype number unused
attr <node>
class number the mark class

mark table a table representing a token list

#### 8.1.2.6 adjust nodes

Valid fields: attr, list

list <node> adjusted material

#### **8.1.2.7** disc nodes

Valid fields: attr, pre, post, replace

field type explanation subtype number indicates the source of a discretionary.  $0 = \text{the } \setminus \text{-command}$ ,  $1 = \text{the } \setminus \text{-command}$ , 2 = added automatically following a -, 3 = added by the hyphenation algorithm

attr <node>
pre <node> pointer to the pre-break text
post <node> pointer to the post-break text
replace <node> pointer to the no-break text

#### 8.1.2.8 math nodes

Valid fields: attr, surround

field type explanation
subtype number 0 = 'on', 1 = 'off'
attr <node>

 $\verb|surround| | number | width of the \verb|\mathsurround| kern |$ 

### **8.1.2.9 glue nodes**

Valid fields: attr, spec, leader

field type explanation subtype number  $0 = \$  internal glue parameters,  $100 = \$   $101 = \$ 

attr <node>

spec <node> pointer to a glue\_spec item

leader <node> pointer to a box or rule for leaders

#### 8.1.2.10 kern nodes

Valid fields: attr, kern

field type explanation subtype number  $0 = \text{from font}, 1 = \text{from } \text{ or } \ \ 2 = \text{from } \text{ accent}$ 

attr <node>

### 8.1.2.11 penalty nodes

Valid fields: attr, penalty

field type explanation
subtype number not used
attr <node>
penalty number

#### 8.1.2.12 glyph nodes

Valid fields: attr, char, font, lang, left, right, uchyph, components, xoffset, yoffset

field	type	explanation
subtype	number	bitfield
attr	<node></node>	
char	number	
font	number	
lang	number	
left	number	
right	number	
uchyph	boolean	
components	<node></node>	pointer to ligature components
xoffset	number	
yoffset	number	

Valid bits for the subtype field are:

#### bit meaning

- 0 character
- 1 glyph
- 2 ligature
- 3 ghost
- 4 left
- 5 right

See section 6.1 for a detailed description of the subtype field.

#### 8.1.2.13 margin\_kern nodes

Valid fields: attr, width, glyph

```
\begin{array}{lll} \textbf{field} & \textbf{type} & \textbf{explanation} \\ \textbf{subtype} & \textbf{number} & 0 = \textbf{left side, 1} = \textbf{right side} \\ \textbf{attr} & < \textbf{node} > \\ \textbf{width} & \textbf{number} \\ \textbf{glyph} & < \textbf{node} > \\ \end{array}
```

### 8.1.3 Math nodes

These are the so—called 'noad's and the nodes that are specifically associated with math processing. Most of these nodes contain sub-nodes so that the list of possible fields is actually quite small. First, the subnodes:

#### 8.1.3.1 Math kernel subnodes

Many object fields in math mode are either simple characters in a specific family or math lists or node lists. There are four associated subnodes that represent these cases (in the following node descriptions these are indicated by the word <kernel>).

The next and prev fields for these subnodes are unused.

#### 8.1.3.1.1 math\_char and math\_text\_char subnodes

Valid fields: attr, fam, char

```
field type explanation
attr <node>
char number
fam number
```

The math\_char is the simplest subnode field, it contains the character and family for a single glyph object. The math\_text\_char is a special case that you will not normally encounter, it arises temporarily during math list conversion (its sole function is to suppress a following italic correction).

#### 8.1.3.1.2 sub\_box and sub\_mlist subnodes

```
Valid fields: attr, list
```

```
field type explanation
attr <node>
list <node>
```

These two subnode types are used for subsidiary list items. For sub\_box, the list points to a 'normal' vbox or hbox. For sub\_mlist, the list points to a math list that is yet to be converted.

#### 8.1.3.2 Math delimiter subnode

There is a fifth subnode type that is used exclusively for delimiter fields. As before, the next and prev fields are unused.

#### 8.1.3.2.1 delim subnodes

```
Valid fields: attr, small_fam, small_char, large_fam, large_char
```

```
field type explanation
attr <node>
small_char number
```

```
small_fam number
large_char number
large_fam number
```

The fields large\_char and large\_fam can be zero, in that case the font that is sed for the small\_fam is expected to provide the large version as an extension to the small\_char.

#### 8.1.3.3 Math core nodes

First, there are the node types that are associated with the simple math objects. All of these have the same list of fields.

#### 8.1.3.3.1 ord, bin, rel, open, close, punct, inner, vcenter, under, over nodes

Valid fields: attr, nucleus, sub, sup

type	explanation
<node></node>	
<kernel></kernel>	
<kernel></kernel>	
<kernel></kernel>	
	<node> <kernel> <kernel></kernel></kernel></node>

#### 8.1.3.3.2 op nodes

Valid fields: attr, nucleus, sub, sup

Operators are a bit special because they also have a sensible subtype.

#### 8.1.3.3.3 accent nodes

Valid fields: attr, nucleus, sub, sup, accent, bot accent

field	type	explanation
attr	<node></node>	
nucleus	<kernel></kernel>	
sub	<kernel></kernel>	
sup	<kernel></kernel>	

```
accent <kernel>
bot_accent <kernel>
```

#### 8.1.3.3.4 style nodes

Valid fields: attr, style

field type explanation
style string contains the style

There are eight possibilities for the string value: one of 'display', 'text', 'script', or 'scriptscript'. Each of these can have a trailing ' to signify 'cramped' styles.

#### **8.1.3.3.5** choice nodes

Valid fields: attr, display, text, script, scriptscript

field	type	explanatior
attr	<node></node>	
display	<node></node>	
text	<node></node>	
script	<node></node>	
scriptscript	<node></node>	

#### 8.1.3.3.6 radical nodes

Valid fields: attr, nucleus, sub, sup, left, degree

```
field type explanation
attr <node>
nucleus <kernel>
sub <kernel>
sup <kernel>
left <delim>
degree <kernel> Only set by \Uroot
```

#### 8.1.3.3.7 fraction nodes

Valid fields: attr, width, num, denom, left, right

```
field type explanation
attr <node>
width number
```

#### 8.1.3.3.8 fence nodes

Valid fields: attr, delim

```
field type explanation
subtype number 1 = \left, 2 = \middle, 3 = \right
attr <node>
delim <delim>
```

### 8.1.4 whatsit nodes

Whatsit nodes come in many subtypes that you can ask for by running node.whatsits(): write (1), close (2), special (3), local\_par (6), dir (7), pdf\_literal (8), pdf\_refobj (10), pdf\_refxform (12), pdf\_refximage (14), pdf\_annot (15), pdf\_start\_link (16), pdf\_end\_link (17), pdf\_dest (19), pdf\_thread (20), pdf\_start\_thread (21), pdf\_end\_thread (22), pdf\_save\_pos (23), pdf\_thread\_data (24), pdf\_link\_data (25), open (0), pdf\_setmatrix (40), pdf\_restore (42), fake (100), late\_lua (35), user\_defined (44), pdf\_colorstack (39), pdf\_save (41), cancel\_boundary (43), close\_lua (36),

#### **8.1.4.1** open nodes

Valid fields: attr, stream, name, area, ext

```
field
          type
                    explanation
attr
          <node>
stream number
                    TFX's stream id number
                    file name
name
          string
          string
                    file extension
ext
                    file area (this may become obsolete)
area
          string
```

#### 8.1.4.2 write nodes

Valid fields: attr, stream, data

field type explanation
attr <node>

```
stream number TEX's stream id number
data table a table representing the token list to be written
```

#### 8.1.4.3 close nodes

Valid fields: attr, stream

field type explanation
attr <node>
stream number TFX's stream id number

#### 8.1.4.4 special nodes

Valid fields: attr, data

field type explanation
attr <node>
data string the \special information

### 8.1.4.5 language nodes

LuaTEX does not have language whatsits any more. All language information is already present inside the glyph nodes themselves. This whatsit subtype will be removed in the next release.

### 8.1.4.6 local\_par nodes

Valid fields: attr, pen\_inter, pen\_broken, dir, box\_left, box\_left\_width, box\_right, box\_right\_width

field	type	explanation
attr	<node></node>	
pen_inter	number	interline penalty
pen_broken	number	broken penalty
dir	string	the direction of this par. see <b>8.1.4.7</b>
box_left	<node></node>	the \localleftbox
box_left_width	number	width of the \localleftbox
box_right	<node></node>	the \localrightbox
box_right_width	number	width of the \localrightbox

#### 8.1.4.7 dir nodes

Valid fields: attr, dir, level, dvi\_ptr, dvi\_h

```
field
                     explanation
           type
attr
           <node>
                     the direction (but see below)
dir
           string
                     nesting level of this direction whatsit
level
           number
dvi ptr
           number
                     a saved dvi buffer byte offset
                     a saved dvi position
dir_h
           number
```

A note on dir strings. Direction specifiers are three-letter combinations of T, B, R, and L.

These are built up out of three separate items:

- the first is the direction of the 'top' of paragraphs.
- the second is the direction of the 'start' of lines.
- the third is the direction of the 'top' of glyphs.

Each of the three items can have 4 separate values, but the directions of the first and second items always have to be perpendicular to each other, which limits the total to 16.

Inside actual dir whatsit nodes, the representation of dir is not a three-letter but a four-letter combination. The first character in this case is always either + or -, indicating whether the value is pushed or popped from the direction stack.

#### 8.1.4.8 pdf\_literal nodes

Valid fields: attr, mode, data

```
field type explanation
attr <node>
mode number the 'mode' setting of this literal
data string the \pdfliteral information
```

#### 8.1.4.9 pdf\_refobj nodes

Valid fields: attr, objnum

```
field type explanation
attr <node>
objnum number the referenced pdf object number
```

#### 8.1.4.10 pdf\_refxform nodes

Valid fields: attr, width, height, depth, objnum.

```
field type explanation
attr <node>
```

```
width
        number
height
        number
depth
        number
                 the referenced pdf object number
objnum number
```

Be aware that pdf\_refxform nodes have dimensions that are used by LuaTEX.

#### 8.1.4.11 pdf\_refximage nodes

Valid fields: attr, width, height, depth, objnum

```
field
         type
                  explanation
attr
         <node>
width
         number
height number
depth
         number
objnum number
                  the referenced pdf object number
```

Be aware that pdf\_refximage nodes have dimensions that are used by LuaTEX.

### 8.1.4.12 pdf\_annot nodes

Valid fields: attr, width, height, depth, objnum, data

```
explanation
field
         type
attr
         <node>
width
         number
height number
depth
         number
objnum number
                  the referenced pdf object number
                  the annotation data
data
         string
```

### 8.1.4.13 pdf\_start\_link nodes

Valid fields: attr, width, height, depth, objnum, link\_attr, action

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
objnum	number	the referenced pdf object number
link_attr	table	the link attribute token list
action	<node></node>	the action to perform

### 8.1.4.14 pdf\_end\_link nodes

Valid fields: attr

field type explanation

attr <node>

### 8.1.4.15 pdf\_dest nodes

Valid fields: attr, width, height, depth, named\_id, dest\_id, dest\_type, xyz\_zoom, objnum

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
${\tt named\_id}$	number	is the dest_id a string value?
dest_id	number or string	the destination id
dest_type	number	type of destination
xyz_zoom	number	
objnum	number	the pdf object number

### 8.1.4.16 pdf\_thread nodes

Valid fields: attr, width, height, depth, named\_id, thread\_id, thread\_attr

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	
$named_id$	number	is the tread_id a string value?
tread_id	number or string	the thread id
thread_attr	number	extra thread information

### 8.1.4.17 pdf\_start\_thread nodes

Valid fields: attr, width, height, depth, named\_id, thread\_id, thread\_attr

field	type	explanation
attr	<node></node>	
width	number	
height	number	
depth	number	

named\_id number is the tread\_id a string value?

thread\_attr number extra thread information

### 8.1.4.18 pdf\_end\_thread nodes

Valid fields: attr

field type explanation

attr <node>

### 8.1.4.19 pdf\_save\_pos nodes

Valid fields: attr

field type explanation

attr <node>

#### 8.1.4.20 late\_lua nodes

Valid fields: attr, reg, data, name

field type explanation

attr <node>

reg number Lua state id number data string data to execute

#### 8.1.4.21 close\_lua nodes

Valid fields: attr, reg

field type explanation

attr <node>

reg number Lua state id number

#### 8.1.4.22 pdf\_colorstack nodes

Valid fields: attr, stack, cmd, data

field type explanation

attr <node>

stack number colorstack id number

cmd number command to execute
data string data

### 8.1.4.23 pdf\_setmatrix nodes

Valid fields: attr, data

field type explanation
attr <node>
data string data

### 8.1.4.24 pdf\_save nodes

Valid fields: attr

field type explanation
attr <node>

#### 8.1.4.25 pdf\_restore nodes

Valid fields: attr

field type explanation
attr <node>

#### 8.1.4.26 user\_defined nodes

User-defined whatsit nodes can only be created and handled from Lua code. In effect, they are an extension to the extension mechanism. The Lua $T \in X$  engine will simply step over such whatsits without ever looking at the contents.

Valid fields: attr, user\_id, type, value

field type explanation attr <node> id number user\_id number type of the value type number value number string <node> table

The type can have one of five distinct values:

## value explanation

116

97 the value is an attribute node list
100 the value is a number
110 the value is a node list
115 the value is a string

the value is a token list in Lua table form

## 9 Modifications

Besides the expected changes caused by new functionality, there are a number of not-so-expected changes. These are sometimes a side-effect of a new (conflicting) feature, or, more often than not, a change necessary to clean up the internal interfaces.

## 9.1 Changes from T<sub>E</sub>X 3.1415926

- See **chapter 6** for many small changes related to paragraph building, language handling, and hyphenation. Most important change: adding a brace group in the middle of a word (like in of{}fice) does not prevent ligature creation.
- There is no pool file, all strings are embedded during compilation.
- plus 1 filll1 does not generate an error. The extra 'l' is simply typeset.
- The \endlinechar can be either added (values 0 or more), or not (negative values). If it is added, the character is always decimal 13 a/k/a ^M a/k/a carriage return (This change may be temporary).
- There is no error given for \outer macros that are expanded inside a group (This change may be temporary).

# 9.2 Changes from $\varepsilon$ -TEX 2.2

- The  $\varepsilon$ -TEX functionality is always present and enabled (but see below about TEXXeT), so the prepended asterisk or -etex switch for iniTEX is not needed.
- TFXXeT is not present, so the primitives

\TeXXeTstate \beginR \beginL \endR \endL

are missing.

- Some of the tracing information that is output by  $\varepsilon$ -TEX's \tracingassigns and \tracingrestores is not there.
- Register management in LuaTEX uses the Aleph model, so the maximum value is 65535 and the implementation uses a flat array instead of the mixed flatGsparse model from  $\varepsilon$ -TEX.
- savinghyphcodes is a no-op. See chapter 6 for details.
- When kpathsea is used to find files, LuaTEX uses the ofm file format to search for font metrics. In turn, this means that LuaTEX looks at the OFMFONTS configuration variable (like Omega and Aleph) instead of TFMFONTS (like TEX and pdfTEX). Likewise for virtual fonts (LuaTEX uses the variable OVFFONTS instead of VFFONTS).

## 9.3 Changes from PDFT<sub>E</sub>X 1.40

- The (experimental) support for snap nodes has been removed, because it is much more natural to build this functionality on top of node processing and attributes. The associated primitives that are now gone are: \pdfsnaprefpoint, \pdfsnapy, and \pdfsnapycomp.
- The (experimental) support for specialized spacing around nodes has also been removed. The associated primitives that are now gone are: \pdfadjustinterwordglue, \pdfprependkern, and \pdfappendkern, as well as the five supporting primitives \knbscode, \stbscode, \shbscode, \knbscode, \shbscode, \knbscode, \shbscode, \shbscode,
- A number of 'utility functions' is removed:

\pdfelapsedtime \pdffilesize \pdfstrcmp

\pdfescapehex \pdflastmatch \pdfunescapehex

\pdfescapename \pdfmatch
\pdfescapestring \pdfmdfivesum
\pdffiledump \pdfresettimer
\pdffilemoddate \pdfshellescape

• A few other experimental primitives are also provided without the extra pdf prefix, so they can also be called like this:

\primitive \ifabsnum \ifprimitive \ifabsdim

- The \pdftexversion is set to 200.
- The PNG transparency fix from 1.40.6 is not applied (high-level support is pending)
- LFS (pdf Files larger than 2GiB) support is not working yet.

## 9.4 Changes from ALEPH RC4

• The input translations from Aleph are not implemented, the related primitives are not available:

\DefaultInputMode \noDefaultInputTranslation

\noDefaultInputMode \noInputTranslation \noInputTranslation

\InputMode \DefaultOutputTranslation \DefaultOutputTranslation \noDefaultOutputTranslation

\noDefaultOutputMode \noOutputTranslation \noOutputTranslation

\OutputMode

\DefaultInputTranslation

- A small series of bounds checking fixes to \ocp and \ocplist has been added to prevent the system from crashing due to array indexes running out of bounds.
- The \hoffset bug when \pagedir TRT is fixed, removing the need for an explicit fix to \hoffset
- A bug causing \fam to fail for family numbers above 15 is fixed.
- Some bits of Aleph assumed 0 and null were identical. This resulted for instance in a bug that sometimes caused an eternal loop when trying to \show a box.

- A fair amount of other minor bugs are fixed as well, most of these related to \tracingcommands output.
- The number of possible fonts, ocps and ocplists is smaller than their maximum Aleph value (around 5000 fonts and 30000 ocps / ocplists).
- The internal function scan\_dir() has been renamed to scan\_direction() to prevent a naming clash.
- The ^^ notation can come in five and six item repetitions also, to insert characters that do not fit in the BMP.
- Glues immediately after direction change commands are not legal breakpoints.
- The \ocp and \ocplist statistics at the end of a run are only printed if OCP's are actually used.

# 9.5 Changes from standard WEB2C

- There is no mltex
- There is no enctex
- The following commandline switches are silently ignored, even in non-Lua mode:

```
-8bit
-translate-file=TCXNAME
-mltex
-enc
-etex
```

- \openout whatsits are not written to the log file.
- Some of the so-called web2c extensions are hard to set up in non-kpse mode because texmf.cnf is not read: shell-escape is off (but that is not a problem because of Lua's os.execute), and the paranoia checks on openin and openout do not happen (however, it is easy for a Lua script to do this itself by overloading io.open).
- The 'E' option does not do anything useful.

# 10 Implementation notes

## 10.1 Primitives overlap

The primitives

\pdfpagewidth \pagewidth
\pdfpageheight \pageheight
\fontcharwd \charwd
\fontcharht \charht
\fontchardp \chardp
\fontcharic \charit

are all aliases of each other.

## 10.2 Memory allocation

The single internal memory heap that traditional TEX used for tokens and nodes is split into two separate arrays. Each of these will grow dynamically when needed.

The texmf.cnf settings related to main memory are no longer used (these are: main\_memory, mem\_bot, extra\_mem\_top and extra\_mem\_bot). 'Out of main memory' errors can still occur, but the limiting factor is now the amount of RAM in your system, not a predefined limit.

Also, the memory (de)allocation routines for nodes are completely rewritten. The relevant code now lives in the C file luanode.c, and basically uses a dozen or so avail lists instead of a doubly-linked model. An extra function layer is added so that the code can ask for nodes by type instead of directly requisitioning a certain amount of memory words.

Because of the split into two arrays and the resulting differences in the data structures, some of the Pascal web macros have been duplicated. For instance, there are now vlink and vinfo as well as link and info. All access to the variable memory array is now hidden behind a macro called vmem.

The implementation of the growth of two arrays (via reallocation) introduces a potential pitfall: the memory arrays should never be used as the left hand side of a statement that can modify the array in question.

The input line buffer and pool size are now also reallocated when needed, and the texmf.cnf settings buf\_size and pool\_size are silently ignored.

## 10.3 Sparse arrays

each had 1.1 million entries with a few memory words each, this makes a major difference in memory usage.

These assignments do not yet show up when using the etex tracing routines \tracingassigns and \tracingrestores (code simply not written yet).

A side-effect of the current implementation is that \global is now more expensive in terms of processing than non-global assignments.

See mathcodes.c and textcodes.c if you are interested in the details.

Also, the glyph ids within a font are now managed by means of a sparse array and glyph ids can go up to index  $2^{21} - 1$ .

## 10.4 Simple single-character csnames

Single-character commands are no longer treated specially in the internals, they are stored in the hash just like the multiletter csnames.

The code that displays control sequences explicitly checks if the length is one when it has to decide whether or not to add a trailing space.

## 10.5 Compressed format

The format is passed through zlib, allowing it to shrink to roughly half of the size it would have had in uncompressed form. This takes a bit more CPU cycles but much less disk I/O, so it should still be faster.

## 10.6 Binary file reading

All of the internal code is changed in such a way that if one of the read\_xxx\_file callbacks is not set, then the file is read by a C function using basically the same convention as the callback: a single read into a buffer big enough to hold the entire file contents. While this uses more memory than the previous code (that mostly used getc calls), it can be quite a bit faster (depending on your I/O subsystem).

# 11 Known bugs and limitations

The bugs below are going to be fixed eventually.

The top ones will be fixed soon, but in the later items either the actual problem is hard to find, or the code that causes the bug is going to be replaced by a new subsystem soon anyway, or it may not be worth the hassle and the limitations will eventually be documented.

- The current linebreaking implementation does not yet take all possible breakpoints into account
  where ligatures are involved in the process. This means that line breaks may change in future
  versions.
- Sometimes font loading via FontForge generates a message like this

```
Bad call to gww_iconv_open, neither arg is UCS4 (EUC-CN->UTF-8)
```

during font loading. This is a limitation of the internal iconv implementation.

- tex.print() and tex.sprint() do not work if \directlua is used in an otp file (in the output of an expression rule).
- Handling of attributes in math mode is not complete. The data structures in math mode are quite different from those in text mode, so this will take some extra effort to implement correctly.
- When used inside \directlua, pdf.print() should create a literal node instead of flushing immediately.
- Not all of Aleph's direction commands are handled properly in pdf mode, and especially the vertical scripts support is missing almost completely (only TRT and TLT are routinely tested).
- Node pointers are not always checked for validity, so if you make a mistake in the node list processing, LuaTEX may terminate itself with an assertion error or 'Emergency stop'.
- In dvi generation mode, using a \textdir switch inside the preamble of a \halign results in overprinted text in the dvi file, because the column width is not taken into account during the final placement phase (this is a bug inherited from Aleph). Also, Aleph apparently dislikes having more than one non-grouped \textdir command in a single lined paragraph.
- Certain constructs in math mode leak memory nodes.

### **12 TODO**

On top of the 'normal' extensions that are planned, there are some more specific small feature requests. Whether these will all be included is not certain yet. New requests are welcome but should fit into our ideas, i.e. no new hard coded solutions. Beware, this is not the roadmap, which is somewhat more ambitious.

- Implement the TFX primitive \dimension, cf. \number.
- Do something about \withoutpt and/or a new register type \real?
- Create callback for the automatic creation of missing characters in fonts.
- Do boxes with dual baselines.
- Make the number of the output box configurable.
- Complete the attributes in math and switch all the nodes to a double-linked list.
- Finish the interface from Lua to TEX's internals, specially the hash and equivalence table (a small subpart is implementing \csname lookups for tex.box access).
- Use of Type1C for embedded PostScript font subsets in traditional 8-bit encodings.
- Support font reencoding of 8-bit fonts via char index instead of via map files.
- Attempt to parse ofm level 0 fonts that are masquerading as level 1.
