Introduction 1

This book will eventually become the reference manual of LuATFX. At the moment, it simply reports the behaviour of the executable matching the snapshot or beta release date in the title page.

Features may come and go. The current version of LUATEX is not meant for production and users cannot depend on stability, nor on functionality staying the same.

Nothing is considered stable just yet. This manual therefore simply reflects the current state of the executable. Absolutely nothing on the following pages is set in stone. When the need arises, anything can (and will) be changed without prior notice.

If you are not willing to deal with this situation, you should wait for the stable version. Currently we expect the first release to be available sometime in the summer of 2008.

LUATEX consists of a number of interrelated but (still) distinguishable parts:

- PDFTEX version 1.40.3
- ALEPH RC4 (from the TEXLIVE repository)
- Lua 5.1.2
- Dedicated Lua libraries
- Various T_FX extensions
- Parts of FontForge 2007.06.07
- Newly written compiled source code to glue it all together

Neither ALEPH's I/O translation processes, nor tcx files, nor ENCTFX can be used, these encoding-related functions are superseded by a Lua-based solution (reader callbacks). Also, some experimental PDFTEX features are removed. These can be implemented in Lua instead.

Basic T_FX enhancements

Version information

There are three new primitives to test the version of LuAT_FX:

| primitive | explanation |
|------------------|---|
| \luatexversion | A combination of major an minor number, as in pdfTeX. Current value: 15 |
| \luatexrevision | The revision, as in pdfTeX. Current value: 0 |
| \luatexdatestamp | A combination of the local date and hour when the current executable was com- |
| | piled, the syntax is identical to \luatexrevision. Value for the executable |
| | that generated this document: 2007102718. |

Note that the \luatexdatestamp depends on both the compilation time and compilation place of the current executable, it is defined in terms of the local time. The purpose of this primitive is solely to be an aid in the development process, do not use it for anything besides debugging.

UNICODE text support

Text input and output is now considered to be UNICODE text, so input characters can use the full range of Unicode $(2^{20} + 2^{16} = 10FFFF = 1114111)$.

Later chapters will talk of characters and glyphs. Although these are not the interchangeable, they are closely related. During typesetting, a character is always converted to a suitable graphic representation of that character in a specific font. However, while processing a list of to-be-typeset nodes, its contents may still be seen as a character. Inside LUATEX there is not yet a clear separation between the two concepts yet. Until this is implemented, please do not be too harsh on us if we make errors in the usage of the terms.

Note: for now, it only makes sense to use values above the base plane ("OxFFFF) for \mathcode and \catcode assignments, since the hyphenation patterns are still limited to at the most 16-bit values, so the other commands will not know what to do with those high values.

A few primitives affected by this, all in a similar fashion: each of them has to accommodate for a larger range of acceptable numbers. For instance, \char now accepts values between 0 and 1114111. This should not be a problem for well-behaved input files, but it could create incompatibilities for input that would have generated an error when processed by older TFX-based engines. The maximum number of allocations is "10FFFF or $2^{20} + 2^{16}$ (21 bits). The maximum value that can be assigned are:

| primitive | bits | hex | numeric |
|-----------|------|--------|-------------------|
| \char | 21 | 10FFFF | $2^{20} + 2^{16}$ |
| \chardef | 21 | 10FFFF | $2^{20} + 2^{16}$ |
| \lccode | 21 | 10FFFF | $2^{20} + 2^{16}$ |

```
\uccode 21 10FFFF 2^{20} + 2^{16}
\sfcode 15 7FFF 2^{15}
\catcode 4 F 2^4
```

As far as the core engine is concerned, all input and output to text files is UTF-8 encoded. Input files can be pre-processed using the reader callback. This will be explained in a later chapter.

Output in byte-sized chunks can be achieved by using characters just outside of the valid unicode range, starting at the value 1.114.112 (0x110000). When the times comes to print a character c >= 1.114.112, LuATFX will actually print the single byte corresponding to c - 1.114.112.

Output to the terminal uses $^$ notation for the lower control range (c < 32), with the exception of $^$ I, $^$ J and $^$ M. These are considered 'safe' and therefore printed as-is.

Normalization of the UNICODE input can be handled by a macro package during callback processing (this will be explained in section 4.6.2).

2.3 Wide math characters

Text handling is now extended up to the full UNICODE range, but math mode deals mostly with glyphs in fonts directly and fonts tend to be 16-bit at maximum. The extension from 8-bit to 16-bit was already present in ALEPH by means of a set of extra primitives.

Therefore, the math primitives from TEX and ALEPH are kept mostly as they are, except for the ones that convert from input to math commands like matcode and omathcode. The traditional TEX primitives are unchanged, their arguments are upscaled from 8 to 16 bits internally (as in ALEPH).

| primitive | max index/bits | hex | numeric |
|---------------|----------------|-----------------|--|
| \mathchardef | 15 | 8000 | $2^3 \times 2^8 \times 2^4$ |
| \mathcode | 15 | 8000 | $2^3 \times 2^8 \times 2^4$ |
| \delcode | 27 | 7FFFFFF | $2^3 \times 2^4 \times 2^8 \times 2^4 \times 2^8$ |
| \mathchar | 15 | 7FFF | $2^3 * 2^8 * 2^4$ |
| \delimiter | 27 | 7FFFFFF | $2^3 * 2^4 * 2^8 * 2^4 * 2^8$ |
| \omathchar | 27 | 7FFFFFF | $2^3 * 2^{16} * 2^8$ |
| \odelimiter | 27+24 | 7FFFFFF + FFFFF | $F 2^3 * 2^8 * 2^{16} + 2^8 * 2^{16}$ |
| \omathchardef | 21=27 | 10FFFF = 800000 | $0 2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$ |
| \omathcode | 21=27 | 10FFFF = 800000 | $0 2^{20} + 2^{16} = 2^3 * 2^{16} * 2^8$ |
| \odelcode | 21 = 27 + 24 | 10FFFF = 7FFFFF | $\mathbf{F} 2^{20} + 2^{16} = 2^3 * 2^8 * 2^{16}$ |
| | | + FFFFF | $F + 2^8 * 2^{16}$ |

2.4 Extended tables

All traditional TEX and ε -TEX registers can be 16 bit numbers as in ALEPH. The affected commands are:

| \count | \countdef | \unhbox | \ht |
|---------|------------|----------|---------|
| \dimen | \dimendef | \unvbox | \dp |
| \skip | \skipdef | \сору | \setbox |
| \muskip | \muskipdef | \unhcopy | \vsplit |
| \marks | \toksdef | \unvcopy | |
| \toks | \box | \wd | |

The same is true for the font-related PDFTFX tables like \rpcode etc.

2.5 Attribute registers

Attributes are a completely new concept in LuATFX. Syntactically, they behave a lot like counters: attributes obey TFX's nesting stack and can be used after \the etc. just like the normal \count registers.

```
\attribute \langle 16-bit number \rangle \langle optional equals \rangle \langle 31-bit number \rangle
\attributedef \langle csname \rangle \langle optional equals \rangle \langle 16-bit number \rangle
```

Conceptually, an attribute is either 'set' or 'unset'. Set attributes can only have values of 0 or more, otherwise they are considered unset and automatically remapped to an special negative value meaning 'unset' (currently that value is -1, but please test on negativity, not on a specific value). All attributes start out in the 'unset' state (in INITEX).

Attributes can be used as extra counter values, but their usefulness comes mostly from the fact that the numbers and values of all 'set' attributes are attached to all nodes created in their scope. These can then be queried from any Lua code that deals with node processing. Future versions of LuaTFX will propably be using specific negative attribute ids for internal use. Further information about how to use attributes for node list processing from lua is given in chapter 7.

LUA related primitives

In order to merge Lua code with TFX input, a few new primitives are needed. LuaTFX has support for 65536 separate Lua interpreter states. States are automatically created based on the integer argument to the primitives \directlua and \latelua.

2.6.1 \directlua

The primitive \directlua is used to execute Lua code immediately. The syntax is

```
\directlua \langle 16-bit number \rangle \langle general text \rangle
```

The (general text) is expanded fully, and then fed into the LuA interpreter state indicated by the $\langle 16$ -bit number \rangle . If the state does not exist yet, it will be initialized automatically. After reading and expansion has been applied to the (general text), the resulting token list is converted to a string as if

it was displayed using \the\toks. On the LuA side, each \directlua block is treated as a separate chunk.

The conversion from and to a token list means that you normally can not use LUA line comments (starting with --) within the argument, as there typically will be only one 'line', so that comment will then run on until the end of the input. You will either need to use TFX-style line comments (starting with %), or change the TFX category codes locally.

The \directlua command is expandable: the results of the LuA code become effective immediately. As an example, the following input:

```
$\pi = \directlua0{tex.print(math.pi)}$
```

will result in $\pi = 3.1415926535898$

Because the (general text) is a chunk, the normal LUA error handling is triggered if there is a problem in the included code. The LUA error messages should be clear enough, but the contextual information is still pretty bad. Typically, you will only see the line number of the right brace at the end of the code.

While on the subject of errors: some of the things you can do inside LUA code can break up LUATEX pretty bad. If you are not careful while working with the node list interface, you may even end up with assertion errors from within the T_FX portion of the executable.

2.6.2 \latelua

\latelua stores LuA code in a whatsit that will be processed inside the output routine. It's intended use is very similar to \pdfliteral. Within the Lua code, you can print PDF statements directly to the PDF file.

\latelua \lambda 16-bit number \rangle \general text \rangle

2.6.3 \luaescapestring

This primitive converts a TFX token sequence so that it can be safely used as the contents of a LUA string: embedded backslashes, double quotes and single quotes are escaped by prepending an extra token consisting of a backslash with category code 12. The token sequence is fully expanded.

```
\luaescapestring \langle general text \rangle
```

Most often, this command is not actually the best way to deal with the differences between the TFX and Lua. In very short bits of Lua code it is often not needed, and for longer stretches of Lua code it is easier to keep the code in a separate file and load it using LUA's dofile:

```
\directlua0 { dofile('mysetups.lua')}
```

2.6.4 \closelua

This primitive allows you to close a LuA state, freeing all of its used memory.

\closelua \langle 16-bit number \rangle

You cannot close the initial LuA state (0), attempts to do so will be silently ignored.

States are never closed automatically except when a fatal out of memory error occurs, at which point LuaTEX will exit anyway.

Also be aware that Lua states are not closed immediately, but only when the \output routine comes into play next (because there may be pending \latelua calls).

2.7 New ε -TFX primitives

2.7.1 \clearmarks

This primitive clears a marks class completely, resetting all three connected mark texts to empty.

\clearmarks \langle 16-bit number \rangle

2.7.2 \noligs and \nokerns

These primitives prohibit ligature and kerning insertion at the time when the initial node list is built by LUATEX's main control loop. They are part of a temporary trick and will be removed in the near future. For now, you need to enable these primitives when you want to do node list processing of 'characters', where TFX's normal processing would get in the way.

```
\noligs (integer)
\nokerns \(\(\)integer\)
```

2.7.3 \formatname

\formatname's syntax is identical to \jobname.

In INITFX, the expansion is empty. Otherwise, the expansion is the value that \jobname had during the INITEX run that dumped the currently loaded format.

2.7.4 \scantextokens

The syntax of \scantextokens is identical to \scantokens.

This is a slightly adapted version of ε -TFX's \scantokens. The differences are:

- The last (and usually only) line does not have a \endlinechar appended
- \scantextokens never raises an EOF error, and it does not execute \everyeof tokens.
- The '.. while end of file ..' error tests are not executed, allowing the expansion to end on a different grouping level or while a conditional is still incomplete.

2.7.5 Catcode tables

Catcode tables are a new feature that allows you to switch to a predefined catcode regime in a single statement. You can have a practically unlimited number of different tables.

The subsystem is backward compatible: if you never use the following commands, your document will not notice any difference in behavior compared to traditional TFX.

The contents of each catcode table is independent of any other catcode tables, and their contents is stored and retrieved from the format file.

2.7.5.1 \catcodetable

```
\catcodetable \langle 28-bit number \rangle
```

The \catcodetable switches to a different catcode table. Such a table has to be previously created using one of the two primitives below, or it has to be zero (table zero is initialized by INITFX).

2.7.5.2 \initcatcodetable

\initcatcodetable \(28\)-bit number \(\)

The \initcatcodetable creates a new table with catcodes identical to those defined by INITEX:

| 0 | \ | | escape |
|----|-----------------|--------|--------------|
| 5 | ^^M | return | car_ret |
| 9 | ^^@ | null | ignore |
| 10 | <space></space> | space | spacer |
| 11 | a z | | letter |
| 11 | A Z | | letter |
| 12 | everything else | | other |
| 14 | % | | comment |
| 15 | ~~? | delete | invalid_char |

The new catcode table is allocated globally: it will not go away after the current group has ended. If the supplied number is identical to the currently active table, an error is raised.

2.7.5.3 \savecatcodetable

\savecatcodetable \(28\)-bit number \(\)

\savecatcodetable copies the current set of catcodes to a new table with the requested number. The definitions in this new table are all treated as if they were made in the outermost level.

The new table is allocated globally: it will not go away after the current group has ended. If the supplied number is the currently active table, an error is raised.

2.7.6 \suppressfontnotfounderror

\suppressfontnotfounderror = 1

If this new integer parameter is non-zero, then $LuaT_EX$ will not complain about font metrics that are not found. Instead it will silently skip the font assignment, making the requested csname for the font \ifx equal to \nullfont, so that it can be tested against that without bothering the user.

2.7.7 Font syntax

LUATEX will accept a braced argument as a font name:

```
\font\myfont = {cmr10}
```

This allows for embedded spaces, without the need for double quotes. Macro expansion takes place inside the argument.

3 LUA general

3.1 Initialization

3.1.1 LUATEX as a LUA interpreter

There are some situations that make LuATFX behaves like it is a LuA interpreter only:

- If a --luaonly option is given on the commandline
- If the executable is named texlua (or luatexlua)
- if the only non-option argument (file) on the commandline has the extension lua or luc.

In this mode, it will set Lua's arg[0] to the found script name, pushing preceding options in negative values and the rest of the commandline in the positive values, just like the Lua interpreter.

LUATEX will exit immediately after executing the specified LUA script and is, in effect, a somewhat bulky standalone LUA interpreter with a bunch of extra preloaded libraries.

3.1.2 LUATEX as a LUA byte compiler

There are two situations that make LuATEX behaves like the LuA byte compiler:

- If a --luaconly option is given on the commandline
- If the executable is named texluac

In this mode, LuaTEX is exactly like luac from the standalone Lua distribution, except that it does not have the -l switch, and that it accepts (but ignores) the --luaconly switch.

3.1.3 Other commandline processing

When the LuaTEX executable starts, it looks for the --lua commandline option. If there is no --lua option, the commandline is interpreted in a similar fashion as in traditional PDFTEX and ALEPH. But if the option is present, LuaTEX will enter an alternative mode of commandline parsing in comparison to the standard web2c programs.

In this mode, a small series of actions is taken in order. At first, it will only interpret a small subset of the commandline directly:

- --lua=s load and execute a LuA initialization script
- --safer disable easily exploitable LUA commands

```
--help display help and exit--version display version and exit
```

Now it searches for the requested LuA initialization script. If it can not be found using the actual name given on the commandline, a second attempt is made by prepending the value of the environment variable LUATEXDIR, if that variable is defined.

Then it checks the **--safer** switch. You can use that to disable some LuA commands that can easily be abused by a malicious document. At the moment, this switch nils the following functions:

library functions os execute exec setenv rename remove io popen output tmpfile lfs rmdir mkdir chdir lock touch

And it makes io.open() fail on files that are opened for anything besides reading.

Next the initialization script is loaded and executed. From within the script, the entire commandline in available in the Lua table arg, beginning with arg[0], containing the name of the executable.

Commandline processing happens very early on. So early, in fact, that none of TEX's initializations have taken place yet. For that reason, the tex, token, node and pdf tables are off-limits during the execution of the startup file (they are nilled). Special care is taken that texio.write and texio.write_nl function properly, so that you can at least report your actions to the log file when (and if) it eventually becomes opened (note that TEX does not even know it's \jobname yet at this point). See chapter 4 for more information about the LuaTEX-specific Lua extension tables.

The Lua initialization script is loaded into Lua state 0, and everything you do will remain visible during the rest of the run, with the exception of the aforementioned tex, token, node and pdf tables: those will be initialized to their documented state after the execution of the script. You should not store anything in variables or within tables with these four global names, as they will be overwritten completely.

We recommend you use the startup file only for your own TEX-independant initializations (if you need any), to parse the commandline, set values in the texconfig table, and register the callbacks you need. LUATEX will fetch some of the other commandline options from the texconfig table at the end of script execution (see the description of the texconfig table later on in this document for more details on which ones exactly).

Unless the texconfig table tells it not to start KPATHSEA at all (set texconfig.kpse_init to false for that), LUATEX acts on three more commandline options after the initialization script is finished:

```
flag meaning
--fmt=s set the format name
--progname=s set the progname (only for KPATHSEA)
--ini enable INITFX mode
```

In order to initialize the built-in KPATHSEA library properly, LUATEX needs to know the correct 'progname' to use, and for that it needs to check -progname (and -ini and -fmt, if -progname is missing).

3.2 LUA changes

The read("*line") function from the io library has been adjusted so that it is line-ending neutral: any of LF, CR or CR+LF are acceptable line endings.

The tostring() printer for numbers has been changed so that it return 0 instead of something like 2e-5 (which confused TEX enormously) when the value is so small that TEX cannot distinguish it from zero.

Dynamic loading of .so and .dll files is disabled on all platforms.

luafilesystem has been extended with two extra boolean functions (isdir(filename) and isfile(filename)) and one extra string field in it's attributes table (permissions).

The string library has an extra function: string.explode(s[,m]). This function returns an array containing the string argument s split into substrings based on the value of the string argument m. The second argument is a string that is either empty (this splits the string into characters), a single character (this splits on each occurrence of that character, possibly introducing empty strings), or a single character followed by the plus sign + (this special version does not create empty substrings). The default value for m is ' +' (multiple spaces).

The **string** library also has six extra iterators that return strings piecemeal:

- string.utfvalues(s) (returns an integer value in the UNICODE range)
- string.utfcharacters(s) (returns a string with a single UTF-8 token in it)
- string.characters(s) (a string containing one byte)
- string.characterpairs(s) (two strings each containing one byte) will produce an empty second string in the string length was odd.
- string.bytes(s) (a single byte value)
- string.bytepairs(s) (two byte values) Will produce nil instead of a number as its second return value if the string length was odd.

The string.characterpairs() and string.bytepairs() are useful especially in the conversion of UTF-16 encoded data into UTF-8.

The os library has a few extra functions and variables:

- os.exec('command') is a non-returning version of os.execute. The advantage of this command is that it cleans out the current process before starting the new one, making it especially useful for use in TEXLUA.
- os.setenv('key','value') This sets a variable in the environment. Passing nil instead of a value string will remove the variable.
- os.env This is a hash table containing a dump of the variables and values in the process environment at the start of the run. It is writeable, but the actual environment is *not* updated automatically.

In stock Lua, many things depend on the current locale. In LuATEX, we can't do that, because it makes documents unportable. While LuATEX is running if forces the following locale settings:

LC_CTYPE=C LC_COLLATE=C LC_NUMERIC=C

3.3 LUA Modules

Some modules that are normally external to Lua are statically linked in with LuaTEX, because they offer useful functionality:

- slnunicode, from the Selene libraries, http://luaforge.net/projects/sln. (version 1.1)
- luazip, from the kepler project, http://www.keplerproject.org/luazip/. (version 1.2.1, but patched for compilation with lua 5.1)
- luafilesystem, also from the kepler project, http://www.keplerproject.org/luafilesystem/. (version 1.2, but patched for compilation with lua 5.1)
- lpeg, by Roberto Ierusalimschy, http://www.inf.puc-rio.br/~roberto/lpeg.html. (version 0.7)
- Izlib, by Tiago Dionizio, http://mega.ist.utl.pt/~tngd/lua/. (version 0.2)
- md5, by Roberto Ierusalimschy http://www.inf.puc-rio.br/~roberto/md5/md5-5/md5.html.

LUATFX LUA Libraries

The interfacing between TFX and Lua is facilitated by a set of library modules. The Lua libraries in this chapter are all defined and initialized by the LuATEX executable. Together, they allow LuA scripts to query and change a number of TFX's internal variables, run various internal functions TFX, and set up LUATEX's hooks to execute Lua code.

The tex library

The tex table contains a large list of virtual internal TEX parameters that are partially writable.

The designation 'virtual' means that these items are not properly defined in LUA, but are only frontends that are handled by a metatable that operates on the actual TEX values. As a result, most of the LUA table operators (like pairs and #) do not work on such items.

At the moment, it is possible to access almost every parameter that has these characteristics:

- You can use it after \the
- It is a single token.

This excludes parameters that need extra arguments, like \the\scriptfont.

The subset comprising simple integer and dimension registers are writable as well as readable (stuff like \tracingcommands and \parindent).

Integer parameters 4.1.1

The integer parameters accept and return LuA numbers.

Read-write:

|----------------|--------------|-----------------|
|----------------|--------------|-----------------|

tex.prevgraf tex.insertpenalties

4.1.2 Dimension parameters

The dimension parameters accept Lua numbers (signifying scaled points) or strings (with included dimension). The result is always a string.

Read-write:

| tex.boxmaxdepth tex.delimitershortfall | <pre>tex.overfullrule tex.pagebottomoffset</pre> | tex.pdfpageheight tex.pdfpagewidth |
|--|--|---------------------------------------|
| tex.displayindent | tex.pageheight | tex.pdfpxdimen |

|----------------------|-----------------|---------------|
| tex.pagefilllstretch | tex.pageshrink | |
| tex.pagefillstretch | tex.pagestretch | |
| tex.pagefilstretch | tex.pagetotal | |

4.1.3 Direction parameters

The direction parameters are read-only and return a LUA string

| tex.bodydir | tex.pagedir | tex.textdir |
|-------------|-------------|-------------|
| tex.mathdir | tex.pardir | |

4.1.4 Glue parameters

All glue parameters are read-only and return a LuA string

```
tex.abovedisplayshortskip tex.lineskip
                                                    tex.tabskip
tex.abovedisplayskip
                         tex.parfillskip
                                                    tex.topskip
tex.baselineskip
                          tex.parskip
                                                    tex.xspaceskip
tex.belowdisplayshortskip tex.rightskip
tex.belowdisplayskip
                          tex.spaceskip
tex.leftskip
                          tex.splittopskip
```

4.1.5 Muglue parameters

All muglue parameters are read-only and return a LUA string

```
tex.medmuskip
                          tex.thinmuskip
tex.thickmuskip
```

4.1.6 Tokenlist parameters

All tokenlist parameters are read-only and return a LUA string

| tex.errhelp | tex.everyjob | ${\tt tex.pdfpageattr}$ |
|------------------|---------------|--------------------------|
| tex.everycr | tex.everymath | tex.pdfpageresources |
| tex.everydisplay | tex.everypar | ${\tt tex.pdfpagesattr}$ |
| tex.everyeof | tex.everyvbox | tex.pdfpkmode |
| tex.everyhbox | tex.output | |

4.1.7 Convert commands

The supported commands at this moment are:

| ${\tt tex.AlephVersion}$ | tex.eTeXrevision | tex.pdfnormaldeviate |
|--------------------------|---------------------|----------------------|
| tex.Alephrevision | tex.formatname | tex.pdftexbanner |
| tex.OmegaVersion | tex.jobname | tex.pdftexrevision |
| tex.Omegarevision | tex.luatexrevision | |
| tex.eTeXVersion | tex.luatexdatestamp | |

All 'convert' commands are read-only and return a Lua string

If you are wondering why this list looks haphazard; these are all the cases of the 'convert' internal command that do not require an argument.

4.1.8 attribute, count, dimension and token registers

TFX's attributes (\attribute), counters (\count), dimensions (\dimen) and token (\toks) registers can be accessed and written to using four virtual sub-tables of the tex table:

```
tex.attribute
                           tex.dimen
tex.count
                           tex.toks
```

It is possible to use the names of relevant \attributedef, \countdef, \dimendef, or \toksdef control sequences as indices to these tables:

```
tex.count.scratchcounter = 0
enormous = tex.dimen['maxdimen']
```

In this case, LUATEX looks up the value for you on the fly. You have to use a valid \countdef (or \attributedef, or \dimendef, or \toksdef), anything else will generate an error (the intent is to eventually also allow <chardef tokens> and even macros that expand into a number)

The attribute and count registers accept and return LuA numbers.

The dimension registers accept Lua numbers (in scaled points) or strings (with an included absolute dimension; em and ex and px are forbidden). The result is always a number in scaled points.

The token registers accept and return LuA strings. LuA strings are converted to and from token lists using \the\toks style expansion: all category codes are either space (10) or other (12).

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setdimen(number n, string s)
tex.setdimen(string s, string s)
tex.setdimen(number n, number n)
tex.setdimen(string s, number n)
number n = tex.getdimen(number n)
number n = tex.getdimen(string s)
tex.setcount(number n, number n)
tex.setcount(string s, number n)
number n = tex.getcount(number n)
number n = tex.getcount(string s)
tex.settoks (number n, string s)
tex.settoks (string s, string s)
string s = tex.gettoks (number n)
string s = tex.gettoks (string s)
```

4.1.9 Box registers

The current dimensions of \box registers can be read and altered using three other virtual sub-tables:

```
tex.wd
tex.ht
tex.dp
```

These are indexed strictly by number.

The box size registers accept LuA numbers (in scaled points) or strings (with included dimension). The result is always a number in scaled points.

As an alternative to array addressing, there are also accessor functions defined:

```
tex.setboxwd(number n, number n)
number n = tex.getboxwd(number n)
tex.setboxht(number n, number n)
number n = tex.getboxht(number n)
tex.setboxdp(number n, number n)
number n = tex.getboxdp(number n)
```

It is also possible to set and query actual boxes, using the node interface as defined in the node library:

```
tex.box
for array access, or
tex.setbox(number n, <node> s)
<node> n = tex.getbox(number n)
for function-based access
Be warned that an assignment like
tex.box[0] = tex.box[2]
```

does not copy the node list, it just duplicates a node pointer. If \box2 will be cleared by TFX commands later on, the contents of \box0 becomes invalid as well. To prevent this from happening, always use node.copy_list() unless you are assigning to a temporary variable:

```
tex.box[0] = node.copy_list(tex.box[2])
```

4.1.10 Print functions

The tex table also contains the three print functions that are the major interface from LuA scripting to T_EX.

The arguments to these three functions are all stored in an in-memory virtual file that is fed to the TFX scanner as the result of the expansion of \directlua.

The total amount of returnable text from a \directlua command is only limited by available system RAM. However, each separate printed string has to fit completely in TFX's input buffer.

4.1.10.1 tex.print

```
tex.print(string s, ...)
tex.print(number n, string s, ...)
```

Each string argument is treated by TEX as a separate input line.

The optional parameter can be used to print the strings using the catcode regime defined by $\colored{catcodetable n}$. If n is not a valid catcode table, then it is ignored, and the currently active catcode regime is used instead.

The very last string of the very last tex.print() command in a \directlua will not have the \endlinechar appended, all others do.

4.1.10.2 tex.sprint

```
tex.sprint(string s, ...)
tex.sprint(number n, string s, ...)
```

Each string argument is treated by TFX as a special kind of input line that makes it suitable for use as a partial line input mechanism:

- TFX does not switch to the 'new line' state, so that leading spaces are not ignored.
- No \endlinechar is inserted.
- Trailing spaces are not removed. (Note that this does not prevent TFX itself from eating spaces as result of interpreting the line. For example, in

```
before\directlua0{tex.sprint("\\relax")tex.sprint(" inbetween")}after
```

the space before inbetween will be gobbled as a result of the 'normal' scanning of \relax).

4.1.10.3 tex.write

```
tex.write(string s, ...)
```

Each string argument is treated by TFX as a special kind of input line that makes is suitable for use as a quick way to dump information:

• All catcodes on that line are either 'space' (for ' ') or 'character' (for all others).

• There is no \endlinechar appended.

4.1.11 Helper functions

4.1.11.1 tex.round

```
number n = tex.round(number o)
```

Rounds lua number o, and returns a number that is in the range of a valid TEX register value. If the number starts out of range, it generates a 'Number to big' error as well.

4.1.11.2 tex.scale

```
number n = tex.scale(number o, number delta)
table n = tex.scale(table o, number delta)
```

Multiplies the lua numbers o and delta, and returns a rounded number that is in the range of a valid TEX register value. In the table version, it creates a copy of the table with all numeric top—level values scaled in that manner. If the mutiplied number(s) are of range, it generates 'Number to big' error(s) as well.

4.2 The token library

The token table contains interface functions to TEX's handling of tokens. These functions are most useful when combined with the token_filter callback, but they could be used standalone as well.

A token is represented in LuA as a small table. For the moment, this table consists of three numeric entries:

| nr | meaning | description |
|----|---------------------|--|
| 1 | command code | this is a value between 0 and 130 (approximately) |
| 2 | command modifier | this is a value between 0 and 2^{21} |
| 3 | control sequence id | for commands that are not te result of control sequences, like letters and |
| | | characters, it is zero, otherwise, it is number pointing into the 'equivalence |
| | | table' |

4.2.1 token.get_next

```
token t = token.get_next()
```

This fetches the next input token from the current input source, without expansion.

4.2.2 token.is_expandable

```
boolean b = token.is_expandable(token t)
```

This tests if the token t could be expanded.

4.2.3 token.expand

```
token.expand()
```

If a token is expandable, this will expand one level of it, so that the first token of the expansion will now be the next token to be read by tex.get next().

4.2.4 token.is activechar

```
boolean b = token.is activechar(token t)
```

This is a special test that is sometimes handy. Discovering whether some token is the result of an active character turned out to be very hard otherwise.

4.2.5 token.create

```
token t = token.create(string csname)
token t = token.create(number charcode)
token t = token.create(number charcode, number catcode)
```

This is the token factory. If you feed it a string, then it is the name of a control sequence (without leading backslash), and it will be looked up in the equivalence table.

If you feed it number, then this is assumed to be an input character, and an optional second number gives its category code. This means it is possible to overrule a character's category code, with a few exceptions: the category codes 0 (escape), 9 (ignored), 13 (active), 14 (comment), and 15 (invalid) cannot occur inside a token. The values 0, 9, 14 and 15 are therefore illegal as input to token.create(), and active characters will be resolved immediately.

Note: unknown string sequences and never defined active characters will result in a token representing an 'undefined control sequence' with a near-random name. It is not possible to define brand new control sequences using token.create!

4.2.6 token.command name

```
string commandname = token.command_name(token t)
```

This returns the name associated with the 'command' value of the token in LUATEX. There is not always a direct connection between these names and primitives. For instance, all \ifxxx tests are grouped under if_fest, and the 'command modifier' defines which test is to be run.

4.2.7 token.command_id

```
number i = token.command_idtring commandname)
```

This returns a number that is the inverse operation of the previous command, to be used as the first item in a token table.

4.2.8 token.csname_name

```
string csname = token.csname name(token t)
```

This returns the name associated with the 'equivalence table' value of the token in LUATFX. It returns the string value of the command used to create the current token, or an empty string if there is no associated control sequence.

4.2.9 token.csname id

```
number i = token.csname id(string csname)
```

This returns a number that is the inverse operation of the previous command, to be used as the third item in a token table.

The node library

The node library contains functions that facilitate dealing with (lists of) nodes and their values. They allow you to alter, create, copy, delete, and insert LUATEX node objects, the core objects within the typesetter.

LUATEX nodes are represented in LUA as userdata with the metadata type luatex.node. The various parts within a node can be accessed using named fields.

Each node has at least the three fields next, id, and subtype:

- The next field returns the userdata object for the next node in a linked list of nodes, or nil, if there is no next node.
- The id indicates TEX's 'node type'. The field id has a numeric value for efficiency reasons, but some of the library functions also accept a string value instead of id.

The subtype is another number. It often gives further information about a node of a particular id, but it is most important when dealing with 'whatsits', because they are differentiated solely based on their subtype.

The other available fields depend on the id (and for 'whatsits', the subtype) of the node. Further details on the various fields and their meanings are given in chapter 7.

TFX's math nodes are not yet supported: there is not yet an interface to the internals of the math list and it is not possible to create them from Lua. Support for unset (alignment) nodes is partial: they can be gueried and modified from LuA code, but not created.

Nodes can be compared to each other, but: you are actually comparing indices into the node memory. This means that equality tests can only be trusted under very limited conditions. It will not work correctly in any situation where one of the two nodes has been freed and/or reallocated: in that case, there will be false positives.

At the moment, memory management of nodes should still be done explicitly by the user. Nodes are not 'seen' by the LUA garbage collector, so you have to call the node free-ing functions yourself when you are no longer in need of a node (list). Nodes form linked lists without reference counting, so you have to be careful that when control returns back to LUATFX itself, you have not deleted nodes that are still referenced from a next pointer elsewhere, and that you did not create nodes that are referenced more than once.

4.3.1 Node handling functions

4.3.1.1 node.types

```
table t = node.types()
```

This function returns an array that maps node id numbers to node type strings, providing an overview of the possible top-level id types.

4.3.1.2 node.whatsits

```
table t = node.whatsits()
```

TFX's 'whatsits' all have the same id. The various subtypes are defined by their subtype. The function is much like node.id, except that it provides an array of subtype mappings.

4.3.1.3 node.id

```
number id = node.id(string type)
```

This converts a single type name to it's internal numeric representation.

4.3.1.4 node.subtype

```
number subtype = node.subtype(string type)
```

This converts a single whatsit name to it's internal numeric representation (subtype).

4.3.1.5 node.type

```
string type = node.type(number id)
```

This converts a internal numeric representation to an external string representation.

4.3.1.6 node.fields

```
table t = node.fields(number id)
table t = node.fields(number id, number subtype)
```

This function returns an array of valid field names for a particular type of node. If you want to get the valid fields for a 'whatsit', you have to supply the second argument also. In other cases, any given second argument will be silently ignored.

This function accepts string id and subtype values as well.

4.3.1.7 node.has_field

```
boolean t = node.has_field(<node> n, string field)
```

This function returns a boolean that is only true if n is actually a node, and it has the field.

4.3.1.8 node.new

```
<node> n = node.new(number id)
<node> n = node.new(number id, number subtype)
```

Creates a new node. All of the new node's fields are initialized to either zero or nil except for id and subtype (if supplied). If you want to create a new whatsit, then the second argument is required, otherwise it need not be present. As with all node functions, this function creates an node on the TEX level.

This function accepts string id and subtype values as well.

4.3.1.9 node.free

```
node.free(<node> n)
```

Removes the node n from T_FX's memory. Be careful: no checks are done on whether this node is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

4.3.1.10 node.flush_list

```
node.flush_list(<node> n)
```

Removes the node list n and the complete node list following n from T_FX 's memory. Be careful: no checks are done on whether any of these nodes is still pointed to from a register or some next field: it is up to you to make sure that the internal data structures remain correct.

4.3.1.11 node.copy

```
<node> m = node.copy(<node> n)
```

Creates a deep copy of node n, including all nested lists as in the case of a hlist or vlist node. Only the **next** field is not copied.

4.3.1.12 node.copy_list

```
<node> m = node.copy_list(<node> n)
```

Creates a deep copy of the node list that starts at n.

4.3.1.13 node.hpack

```
<node> h = node.hpack(<node> n)
<node> h = node.hpack(<node> n, number w, string info)
```

This function creates a new hlist by packaging the list that begins at node n into a horizontal box. With only a single argument, this box is created using the natural width of it's components. In the three argument form, info must be either additional or exactly, and w is the additional (\hbox spread) or exact (\hbox to) width to be used.

Caveat: at this moment, there can be unexpected side-effects to this function, like updating some of the \marks and \inserts.

4.3.1.14 node.slide

```
<node> m = node.slide(<node> n)
```

Returns the last node of the node list that starts at n. As a side-effect, it also creates a reverse chain of prev pointers between nodes.

4.3.1.15 node.length

```
number i = node.length(<node> n)
number i = node.length(<node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at n. If m is also supplied it stops at m instead of at the end of the list. The node m is not counted.

4.3.1.16 node.count

```
number i = node.count(number id, <node> n)
number i = node.count(number id, <node> n, <node> m)
```

Returns the number of nodes contained in the node list that starts at n that have an matching id field. If m is also supplied, counting stops at m instead of at the end of the list. The node m is not counted.

This function also accept string id's.

4.3.1.17 node.traverse

```
<node> t = node.traverse(<node> n)
<node> t = node.traverse(<node> n, <node> m)
```

This is an iterator that loops over the node list that starts at n. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

4.3.1.18 node.traverse_id

```
<node> t = node.traverse_id(number id, <node> n, <node> m)
<node> t = node.traverse id(number id, <node> n)
```

This is an iterator that loops over all the nodes in the list that starts at n that have a matching id field. If m is also supplied, the iterator stops at m instead of at the end of the list. The node m is not processed.

This function also accept string id's.

4.3.1.19 node.remove

```
<node> head, current = node.remove(<node> head, <node> current)
```

This function removes the node current from the list following head. It is your responsibility to make sure it is really part of that list. The return values are the new head and current nodes. The returned current is the node in the calling argument, and is only passed back as a convenience (it's next field will be cleared). The returned head is more important, because if the function is called with current equal to head, it will be changed.

4.3.1.20 node.insert_before

```
<node> head, new = node.insert_before(<node> head, <node> current, <node>
new)
```

This function inserts the node new before current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the (potentially mutated) head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

4.3.1.21 node.insert_after

```
<node> head, new = node.insert after(<node> head, <node> current, <node>
new)
```

This function inserts the node new after current into the list following head. It is your responsibility to make sure that current is really part of that list. The return values are the head and the new, set up to be part of the list (with correct next field). If head is initially nil, it will become new.

4.3.1.22 node.first_character

```
<node> n = node.first_character(<node> n)
<node> n = node.first_character(<node> n, <node> m)
```

Returns the first node that is a glyph node with a subtype indicating it is a character, or nil.

4.3.1.23 node.ligaturing

```
node.ligaturing(<node> n)
node.ligaturing(<node> n, <node> m)
```

Apply T_FX-style ligaturing to the specified nodelist.

4.3.1.24 node.kerning

```
node.kerning(<node> n)
node.kerning(<node> n, <node> m)
```

Apply T_FX-style kerning to the specified nodelist.

4.3.2 Attribute handling

Attributes appear as linked list of userdata objects in the attr field of individual nodes. They can be handled individually, but it much safer and more efficient to use the dedicated functions associated with them.

4.3.2.1 node.has_attribute

```
number v = node.has_attribute(<node> n, number id)
number v = node.has_attribute(<node> n, number id, number val)
```

Tests if a node has the attribute with number id set. If val is also supplied, also tests if the value matches val. It returns the value, or, if no match is found, nil.

4.3.2.2 node.set_attribute

```
node.set_attribute(<node> n, number id, number val)
```

Sets the attribute with number id to the value val. Duplicate assignments are ignored.

4.3.2.3 node.unset_attribute

```
number v = node.unset_attribute(<node> n, number id, number val)
number v = node.unset attribute(<node> n, number id)
```

Unsets the attribute with number id. If val is also supplied, it will only perform this operation if the value matches val. Missing attributes or attribute-value pairs are ignored.

If the attribute was actually deleted, returns its old value. Otherwise, returns nil.

4.4 The texio library

This library takes care of the low-level I/O interface.

4.4.1 Printing functions

4.4.1.1 texio.write

```
texio.write(string target, string s)
texio.write(string s)
```

Without the target argument, writes the string to the same location(s) TFX writes messages to at this moment. If \batchmode is in effect, it writes only to the log, otherwise it writes to the log and the terminal.

The optional target can be one of three possibilities: term, log or term and log.

4.4.1.2 tex.write_nl

```
texio.write_nl(string target, string s)
texio.write_nl(string s)
```

Like texio.write, but make sure that the string s will appear at the beginning of a line. You can use an empty string if you only want to move to the next line.

4.5 The pdf library

This table contains the current h en v values that define the location on the output page. The values can be queried and set using scaled points as units.

```
pdf.v
pdf.h
```

The associated function calls are

```
pdf.setv(number n)
number n = pdf.getv()
pdf.seth(number n)
number n = pdf.geth()
```

It also holds a print function to write stuff to the PDF document, that can be used from within a \latelua argument. This function is not to be used inside \directlua unless you know exactly what you are doing.

pdf.print

```
pdf.print(string s)
pdf.print(string type, string s)
```

The optional parameter can be used to mimic the behaviour of \pdfliteral: the type is direct or page.

The callback library

This library has functions that register, find and list callbacks.

The callback library is only available in LuA state zero (0).

```
callback.register(string callback name, function callback func)
callback.register(string callback_name,nil)
```

where the callback_name is a predefined callback name, see below.

LuaTEX internalizes the callback function in such a way that it does not matter if you redefine a function accidentally.

Callback assignments are always global. You can use the special value nil instead of a function for clearing the callback.

```
table info = callback.list()
```

The keys in the table are the known callback names, the value is a boolean where true means that the callback is currently set (active).

```
function f = callback.find(callback name)
```

If the callback is not set, callback.find returns nil.

4.6.1 File discovery callbacks

```
4.6.1.1 find_read_file and find_write_file
```

You callback function should have the following conventions:

```
string actual_name = function (number id_number, string asked_name)
```

Arguments:

id_number

This number is zero for the log or \input files. For TFX's \read or \write the number is incremented by one, so \read0 becomes 1.

asked_name

This is the user-supplied filename, as found by \input, \openin or \openout.

Return value:

actual_name

This is the filename used. For the very first file that is read in by TFX, you have to make sure you return an actual name that has an extension and that is suitable for use as jobname. If you don't, you will have to manually fix the name of the log file and output file after LUATFX is finished, and an eventual format filename will become mangled. That is because these file names depend on the jobname.

You have to return nil if the file cannot be found.

4.6.1.2 find_font_file

Your callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked name is an OTF or TFM font metrics file.

Return **nil** if the file cannot be found.

4.6.1.3 find_output_file

You callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked name is the PDF or DVI file for writing.

4.6.1.4 find format file

You callback function should have the following conventions:

```
string actual_name = function (string asked_name)
```

The asked name is a format file for reading (the format file for writing is always opened in the current directory).

4.6.1.5 find_vf_file

Like find_font_file, but for virtual fonts. This applies to both ALEPH's OVF files and traditional Knuthian vF files.

4.6.1.6 find_ocp_file

Like find_font_file, but for ocp files.

4.6.1.7 find map file

Like find_font_file, but for map files.

4.6.1.8 find enc file

Like find_font_file, but for enc files.

4.6.1.9 find sfd file

Like find_font_file, but for subfont definition files.

4.6.1.10 find_pk_file

Like find_font_file, but for pk bitmap files. The argument name is a bit special in this case. It's form is

<base res>dpi/<fontname>.<actual res>pk

So you may be asked for 600dpi/manfnt.720pk. It is up to you to find a 'reasonable' bitmap file to go with that specification.

4.6.1.11 find_data_file

Like find_font_file, but for embedded files (\pdfobj file '...').

4.6.1.12 find_opentype_file

Like find font file, but for OpenType font files.

4.6.1.13 find_truetype_file and find_type1_file

You callback function should have the following conventions:

string actual_name = function (string asked_name)

The asked_name is a font file. This callback is called while LUATFX is building its internal list of needed font files, so the actual timing may surprise you. Your return value is later fed back into the matching read file callback.

Strangely enough, find_type1_file is also used for OpenType (otf) fonts.

4.6.1.14 find_image_file

You callback function should have the following conventions:

```
string actual name = function (string asked name)
```

The asked_name is an image file. Your return value is used to open a file from the harddisk, so make sure you return something that is considered the name of a valid file by your operating system.

4.6.2 File reading callbacks

4.6.2.1 open_read_file

You callback function should have the following conventions:

```
table env = function (string file_name)
```

Argument:

file_name

the filename returned by a previous find_read_file or the return value of kpse.find_file() if there was no such callback defined.

Return value:

env

this is a table containing at least one required and one optional callback functions for this file. The required field is reader and the associated function will be called once for each new line to be read, the optional one is close that will be called once when LUATEX is done with the file.

LUATEX never looks at the rest of the table, so you can use it to store your private per-file data. Both the callback functions will receive the table as their only argument.

4.6.2.1.1 reader

LUATEX will run this function whenever it needs a new input line from the file.

```
function(table env)
    return string line
end
```

Your function should return either a string or nil. The value nil signals that the end of file has occurred, and will make TFX call the optional close function next.

4.6.2.1.2 close

LUATEX will run this optional function when it decides to close the file.

```
function(table env)
    return
end
```

Your function should not return any value.

4.6.2.2 General file readers

There is a set of callbacks for the loading of binary data files. These all use the same interface:

```
function(string name)
    return boolean success, string data, number data_size
end
```

The name will normally be a full path name as it is returned by either one of the file discovery callbacks or the internal version of kpse.find_file().

```
success
   return false when a fatal error occured (e.g. when the file cannot be found, after all).
data
   the bytes comprising the file.
data_size
   the length of the data, in bytes.
```

return an empty string and zero if the file was found but there was a reading problem.

The list of functions is:

```
This function is called when TEX needs to read a ofm or tfm file.
read_font_file
read_vf_file
                         for virtual fonts.
read ocp file
                         for ocp files.
                         for map files.
read_map_file
                         for encoding files.
read_enc_file
read_sfd_file
                         for subfont definition files.
```

```
read_pk_file
                       for pk bitmap files.
read_data_file
                       for embedded files (\pdfobj file '...').
read_truetype_file for TRUETYPE font files.
read_type1_file
                       for Type1 font files.
read_opentype_file for OpenType font files.
```

4.6.3 Data processing callbacks

4.6.3.1 process_input_buffer

This callback allows you to change the contents of the line input buffer just before LUATEX actually starts looking at it.

```
function(string buffer)
    return string adjusted_buffer
end
```

If you return nil, LuaTFX will pretend like your callback never happened. You can gain a small amount of processing time from that.

4.6.3.2 token filter

This callback allows you to replace the way LUATEX fetches lexical tokens.

```
function()
    return table token
end
```

The calling convention for this callback is bit more complicated than for most other callbacks. The function should either return a LuA table representing a valid to-be-processed token or tokenlist, or something else like nil or an empty table.

If your LUA function does not return a table representing a valid token, it will be immediately called again, until it eventually does return a useful token or tokenlist (or until you reset the callback value to nil). See the description of token for some handy functions to be used in conjunction with this callback.

If your function returns a single usable token, then that token will be processed by LUATEX immediately. If the function returns a token list (a table consisting of a list of consecutive token tables), then that list will be pushed to the input stack as completely new token list level, with it's token type set to 'inserted'. In either case, the returned token(s) will not be fed back into the callback function.

4.6.4 Node list processing callbacks

The description of nodes and node lists is in chapter 7.

4.6.4.1 buildpage_filter

This callback is called whenever LUATEX is ready to move stuff to the main vertical list. You can use this callback to do specialized manipulation of the page building stage like imposition or column balancing.

```
function(<node> head, string extrainfo)
    return true | false | <node> newhead
end
```

As for all the callbacks that deal with nodes, the return value can be one of three things:

- boolean true signals successful processing
- node signals that the 'head' node should be replaced by this node
- boolean false signals that the 'head' node list should be ignored and flushed from memory

The string extrainfo gives some additional information about what TEX's state is with respect to the 'current page'. The possible values are:

| value | explanation |
|----------------|--------------------------------------|
| alignment | a (partial) alignment is being added |
| box | a typeset box is being added |
| begin_of_par | the beginning of a new paragraph |
| vmode_par | \par was found in vertical mode |
| hmode_par | \par was found in horizontal mode |
| insert | an insert is added |
| penalty | a penalty (in vertical mode) |
| before_display | immediately before a display starts |
| after_display | a display is finished |

4.6.4.2 pre_linebreak_filter

This callback is called just before LUATEX starts converting a list of nodes into a stack of \hboxes. The removal of a possible final skip and the subsequent insertion of \parfillskip has not happened yet at that moment.

```
function(<node> head, string groupcode)
    return true | false | <node> newhead
end
```

The string called groupcode identifies the nodelist's context within TFX's processing. range of possibilities is given in the table below, but not all of those can actually appear in pre_linebreak_filter, some are for the hpack_filter and vpack_filter callbacks that will be explained in the next two paragraphs.

value explanation

hbox \hbox in horizontal mode adjusted_hbox \hbox in vertical mode

vbox \vbox \vtop vtop

\halign or \valign align

discretionaries disc packaging an insert insert

vcenter \vcenter

local box \localleftbox or \localrightbox

split_off top of a \vsplit split_keep remainder of a \vsplit

align_set alignment cell alignment row fin_row

4.6.4.3 hpack filter

This callback is called when TEX is ready to start boxing some horizontal mode material. Math items are ignored at the moment.

```
function(<node> head, string groupcode, number size, string packtype)
    return true | false | <node> newhead
end
```

The packtype is either additional or exactly. If additional, then the size is a \hbox spread ... argument. If exactly, then the size is a \hbox to In both cases, the number is in scaled points.

4.6.4.4 vpack_filter

This callback is called when TFX is ready to start boxing some vertical mode material. Math displays are ignored at the moment.

This function is very similar to the hpack_filter. Besides the fact that it is called at different moments, there is an extra variable that matches TEX's \maxdepth setting.

```
function(<node> head, string groupcode, number size, string packtype,
ber maxdepth)
    return true | false | <node> newhead
end
```

4.6.4.5 pre_output_filter

This callback is called when TFX is ready to start boxing the box 255 for \output.

```
function(<node> head, string groupcode, number size, string packtype, num-
ber maxdepth)
    return true | false | <node> newhead
end
```

4.6.4.6 hyphenate

```
function(<node> head, <node> tail)
end
```

No return values. This callback has to insert discretionary nodes in the node list it receives.

4.6.4.7 ligaturing

```
function(<node> head, <node> tail)
end
```

No return values. This callback has to apply ligaturing to the node list it receives.

4.6.4.8 kerning

```
function(<node> head, <node> tail)
end
```

No return values. This callback has to apply kerning between the nodes in the node list it receives.

4.6.5 Information reporting callbacks

```
4.6.5.1 start_run
```

```
function()
```

Replaces the code that prints LuATEX's banner

4.6.5.2 stop_run

```
function()
```

Replaces the code that prints LuATEX's statistics and 'output written to' messages.

4.6.5.3 start_page_number

function()

Replaces the code that prints the [and the page number at the begin of \shipout. This callback will also override the printing of box information that normally takes place when \tracingoutput is positive.

4.6.5.4 stop_page_number

function()

Replaces the code that prints the] at the end of \shipout

4.6.5.5 show_error_hook

```
function()
    return
end
```

This callback is run from inside the TEX error function, and the idea is to allow you to do some extra reporting on top of what TFX already does (none of the normal actions are removed). You may find some of the values in the status table useful.

message

is the formal error message TFX has given to the user (the line after the '!') indicator

is either a filename (when it is a string) or a location indicator (a number) that can means lots of different things like a token list id or a \read number.

lineno

is the current line number

This is an investigative item for 'testing the water' only. The final goal is the total replacement of TFX's error handling routines, but that needs lots of adjustments in the web source because TFX deals with errors in a somewhat haphazard fashion. This is why the exact definition of indicator is not given here.

4.6.6 Font-related callbacks

4.6.6.1 define font

```
function(string name, number size, number id) return table font end
```

The string name is the filename part of the font specification, as given by the user.

The number size is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the font table that is to be returned is explained in chapter 6. That table is saved internally, so you can put extra fields in the table for your later LUA code to use.

4.7 The lua library

This library contains two read-only items:

4.7.1 Variables

```
number n = lua.id
```

This returns the id number of the instance.

```
string s = lua.version
```

This returns a LuaTEX version identifier string. The value is currently lua.version, but it is soon to be replaced by something more elaborate.

4.7.2 LUA bytecode registers

Lua registers can be used to communicate Lua functions across Lua states. The accepted values for assignments are functions and nil. Likewise, the retrieved value is either a function or nil.

```
lua.bytecode[n] = function () .. end
lua.bytecode[n]()
```

The contents of the lua.bytecode array is stored inside the format file as actual LUA bytecode, so it can also be used to preload lua code.

The associated function calls are

```
function f = lua.getbytecode(number n)
lua.setbytecode(number n, function f)
```

4.8 The kpse library

4.8.1 kpse.find_file

'graphic/figure'

The most important function in the library is find_file:

```
string f = kpse.find file(string filename)
string f = kpse.find_file(string filename, string ftype)
string f = kpse.find file(string filename, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, boolean mustexist)
string f = kpse.find_file(string filename, string ftype, number dpi)
Arguments:
filename
   the name of the file you want to find, with or without extension.
   maps to the -format argument of KPSEWHICH. The supported ftype values are the same as the
   ones supported by the standalone kpsewhich program:
    'pk'
                                              'TeX system documentation'
    'bitmap font'
                                              'texpool'
    'tfm'
                                              'TeX system sources'
    'afm'
                                              'PostScript header'
    'base'
                                              'Troff fonts'
    'bib'
                                              'type1 fonts'
    'bst'
                                              'vf'
    'cnf'
                                              'dvips config'
    'ls-R'
                                              'ist'
    'fmt'
                                              'truetype fonts'
                                              'type42 fonts'
    'map'
                                              'web2c files'
    'mem'
    'mf'
                                              'other text files'
    'mfpool'
                                              'other binary files'
                                              'misc fonts'
    'mft'
    'mp'
                                              'web'
                                              'cweb'
    'mppool'
    'MetaPost support'
                                              'enc files'
    'ocp'
                                              'cmap files'
                                              'subfont definition files'
    'ofm'
    'opl'
                                              'opentype fonts'
                                              'pdftex config'
    'otp'
    'ovf'
                                              'lig files'
    'ovp'
                                              'texmfscripts'
```

The default type is tex.

mustexist

is similar to KPSEWHICH'S -must-exist, and the default is false. If you specify true (or a non-zero integer), then the KPSE library will search the disk as well as the 1s-R databases. dpi

This is used for the size argument of the formats pk, gf, and bitmap font.

4.8.2 kpse.set program name

Sets the KPATHSEA executable (and optionally program) name

```
kpse.set_program_name(string name)
kpse.set_program_name(string name, string progname)
```

The second argument controls the use of the 'dotted' values in the texmf.cnf configuration file, and defaults to the first argument.

4.8.3 kpse.init prog

Extra initialization for programs that need to generate bitmap fonts.

```
kpse.init_prog(string prefix, number base_dpi, string mfmode)
kpse.init_prog(string prefix, number base_dpi, string mfmode, string fall-
back)
```

4.8.4 kpse.readable file

Test if an (absolute) file name is a readable file

```
string f = kpse.readable_file(string name)
```

The return value is the actual absolute filename you should use, because the disk name is not always the same as the requested name, due to aliases and system-specific handling under e.g. MSDOS.

Returns nil if the file does not exist or is not readable.

4.8.5 kpse.expand path

```
Like kpsewhich's -expand-path:
```

```
string r = kpse.expand_path(string s)
```

4.8.6 kpse.expand_var

```
Like kpsewhich's -expand-var:
```

```
string r = kpse.expand var(string s)
```

4.8.7 kpse.expand braces

```
Like kpsewhich's -expand-braces:
```

```
string r = kpse.expand_braces(string s)
```

4.8.8 kpse.var_value

```
Like kpsewhich's -var-value:
```

```
string r = kpse.var_value(string s)
```

4.9 The status library

This contains a number of run-time configuration items that you may find useful in message reporting, as well as an iterator function that gets all of the names and values as a table.

```
table info = status.list()
```

The keys in the table are the known items, the value is the current value.

Almost all of the values in status are fetched through a metatable at run-time whenever they are accessed, so you cannot use pairs on status, but you can use pairs on info, of course.

If you do not need the full list, you can also ask for a single item by using it's name as an index into status.

The current list is:

| key | explanation |
|------------------|-----------------------------|
| pdf_gone | written PDF bytes |
| pdf_ptr | not yet written PDF bytes |
| dvi_gone | written DVI bytes |
| dvi_ptr | not yet written DVI bytes |
| total_pages | number of written pages |
| output_file_name | name of the PDF or DVI file |
| log_name | name of the log file |
| banner | terminal display banner |

var_used variable (one-word) memory in use
dyn_used token (multi-word) memory in use

str_ptr number of strings

init_str_ptr number of INITEX strings max_strings maximum allowed strings

pool_size current size allocated for string characters
var_mem_max number of allocated words for nodes
fix_mem_max number of allocated words for tokens
fix_mem_end maximum number of used tokens
cs_count number of control sequences

hash_size size of hash
hash_extra extra allowed hash
font_ptr number of active fonts
hyph_count hyphenation exceptions

hyph_size max used hyphenation exceptions
max_in_stack max used input stack entries
max_nest_stack max used nesting stack entries
max_param_stack max used parameter stack entries

max_buf_stack max used buffer position
max_save_stack max used save stack entries

output_active

4.10 The texconfig table

This is a table that is created empty. A startup LUA script could fill this table with a number of settings that are read out by the executable after loading and executing the startup file.

| key | type | default | explanation |
|-------------------------------------|---------|------------|---|
| string_vacancies | number | 75000 | cf. web2c docs |
| pool_free | number | 5000 | cf. web2c docs |
| max_strings | number | 15000 | cf. web2c docs |
| strings_free | number | 100 | cf. web2c docs |
| trie_size | number | 20000 | cf. web2c docs |
| hyph_size | number | 659 | cf. web2c docs |
| nest_size | number | 50 | cf. web2c docs |

| jobname | string | if no input file name was given on the comman- dline, this key will be tested first instead of simply giving up |

4.11 The font library

The font library provides the interface into the internals of the font system, and also it contains helper functions to load traditional TFX font metrics formats. Other font loading functionality is provided by the fontforge library that will be discussed in the next section.

Loading a TFM file 4.11.1

```
table fnt = font.read_tfm(string name, number s)
```

The number is a bit special:

- if it is positive, it specifies an 'at size' in scaled points.
- if it is negative, its absolute value represents a 'scaled' setting relative to the designsize of the font.

The internal structure of the metrics font table that is returned is explained in chapter 6.

4.11.2 Loading a VF file

```
table vf_fnt = font.read_vf(string name, number s)
```

The meaning of the number s, and the format of the returned table is the silimar to the read_tfm() function.

4.11.3 The fonts array

The whole table of TEX fonts is accessible from lua using a virtual array.

```
font.fonts[n] = { ... }
table f = font.fonts[n]
```

See chapter 6 for the structure of the tables. Because this is a virtual array, you cannot call pairs on it, but see below for the font.each iterator.

The two metatable functions implementing the virtual array are:

```
table f = font.getfont(number n)
font.setfont(number n, table f)
```

Also note the following: assignments can only be made to fonts that have already been defined in TFX, but have not been accessed at all since that definition. This limits the usability of the write access to font.fonts quite a lot, a less stringent ruleset will likely be implemented later.

4.11.4 Checking a font's status

You can test for the status of a font by calling this function:

```
boolean f = font.frozen(number n)
```

The return value is one of true (unassignable), false (can be changed) or nil (not a valid font at all).

4.11.5 Defining a font directly

You can define your own font into font.fonts

```
number i = font.define(table f)
```

The return value is the internal id number of the defined font (the index into font.fonts). If the font creation fails, an error is raised. The table is a font structure, as explained in chapter 6.

4.11.6 Currently active font

```
number i = font.current();
font.current(number i);
```

This gets or sets the currently used font number.

4.11.7 Maximum font id

```
number i = font.max();
```

This is the largest used index in font.fonts.

4.11.8 Iterating over all fonts

```
for i,v in font.each() do
   ...
end
```

This is an iterator over each of the defined TEX fonts. The first returned value is the index in font.fonts, the second the font itself, as a lua table. The indices are listed incrementally, but they do not always form an array of consecutive numbers: in some cases there can be holes in the sequence.

4.12 The fontforge library

4.12.1 Getting quick information on a font

```
local info = fontforge.info('filename')
```

This function returns either nil, or a table, or an array of small tables (in the case of a TrueType collection). The returned table(s) will contain six fairly interesting information items from the font(s) defined by the file:

| key | type | explanation |
|-------------|--------|---|
| fontname | string | the 'PostScript' name of the font |
| fullname | string | The formal name of the font |
| familyname | string | The family name this font belongs to |
| weight | string | A string indicating the color value of the font |
| version | string | The internal font version |
| italicangle | float | The slant angle |

Getting information through this function is (sometimes much) more efficient than loading the font properly, and is therefore handy when you want to create a dictionary of available fonts based on a directory contents.

4.12.2 Loading an OPENTYPE or TRUETYPE file

If you want to use an OpenType font, you have to get the metric information from somewhere. Using the fontforge library, the basic way to get that information is thus:

```
function load_font (filename)
  local metrics = nil
  local font = fontforge.open(filename)
  if font then
    metrics = fontforge.to_table(font)
    fontforge.close(font)
```

```
end
return metrics
end

myfont = load_font('/opt/tex/texmf/fonts/data/arial.ttf')
```

The main function call is

```
f, w = fontforge.open('filename')
```

The first return value is a table representation of the font. The second return value is a table containing any warnings and errors reported by fontforge while opening the font. In normal typesetting, you would probably ignore the second argument, but it can be useful for debugging purposes.

For TRUETYPE collections (when filename ends in 'ttc'), you have to use a second string argument to specify which font you want from the collection. Use one of the fullname strings that are returned by fontforge.info for that.

```
f, w = fontforge.open('filename', 'fullname')
```

The font file is parsed and partially interpreted by the font loading routines from FontForge. The file format can be OpenType, TrueType, TrueType Collection, CFF, or Type1.

There are a few advantages to this approach compared to reading the actual font file ourselves:

- The font is automatically re-encoded, so that the metrics table for TRUETYPE and OPENTYPE fonts is using UNICODE for the character indices.
- Many features are pre-processed into a format that is easier to handle than just the bare tables would be.
- PostScript-based OpenType fonts do not store the character height and depth in the font file, so the character boundingbox has to be calculated in some way.
- In the future, it may be interesting to allow LuA scripts access to the font program itself, perhaps even creating or changing the font.

4.12.3 Applying a 'feature file'

You can apply a 'feature file' to a loaded font:

```
fontforge.apply_featurefile(f,'filename')
```

A 'feature file' is a textual representation of the features in an OpenType font. See http://www.adobe.com/devnet/opentype/afdko/topic_feature_file_syntax.html and http://fontforge.sourceforge.net/feature-file.html for a more detailed description of feature files.

4.12.4 Applying an 'afm file'

You can apply a 'afm file' to a loaded font:

```
fontforge.apply_afmfile(f,'filename')
```

An 'afm file' is a textual representation of (some of) the metainformation in a Type 1 font. See http: //www.adobe.com/devnet/font/pdfs/5004.AFM_Spec.pdf for more information about afm files.

Note: if you fontforge.open() a PFB file named font.pfb, the library will automatically search for, and apply, font.afm if it exists in the same directory as font.pfb. In that case, there is no need for an explicit call to apply_afmfile().

Fontforge font tables 4.13

The top-level keys in the returned table are (the explanations in this part of the documentation is not yet finished):

| key | type | explanation |
|------------------------------|--------|--|
| table_version | number | indicates the metrics version |
| fontname | string | PostScript font name |
| fullname | string | official font name |
| familyname | string | family name |
| weight | string | weight indicator |
| copyright | string | copyright information |
| filename | string | the file name |
| version | string | font version |
| italicangle | float | slant angle |
| units_per_em | number | 1000 for PostScript-based fonts, usually 2048 for |
| | | TrueType |
| ascent | number | height of ascender in units_per_em |
| descent | number | depth of descender in units_per_em |
| upos | float | |
| uwidth | float | |
| vertical_origin | number | |
| uniqueid | number | |
| glyphcnt | number | number of included glyphs |
| glyphs | array | |
| glyphmax | number | maximum used index the glyphs array |
| hasvmetrics | number | |
| order2 | | set to 1 for TrueType splines, 0 otherwise |
| strokedfont | number | |
| weight_width_slope_only | number | |
| head_optimized_for_cleartype | number | |
| uni_interp | enum | unset, none, adobe, greek, japanese, trad_chinese, |
| | | simp_chinese, korean, ams |
| origname | string | the file name, as supplied by the user |

table mapprivate table xuid string pfminfo table names table cidinfo table subfonts array cidmaster array commments string anchor_classes table ttf_tables table table kerns vkerns table texdata table table lookups gpos table table gsub chosenname string macstyle number fondname string design_size number fontstyle_id number fontstyle_name table design_range_bottom number number design_range_top strokewidth float mark_classes array mark_class_names array creationtime number modificationtime number os2_version number

1 Glyph items

The glyphs is an array containing the per-character information (quite a few of these are only present if nonzero).

| key | type | explanation |
|--------------|--------|-----------------------------|
| name | string | the glyph name |
| unicodeenc | number | unicode code point, or -1 |
| boundingbox | array | array of four numbers |
| width | number | (only for horizontal fonts) |
| vwidth | number | (only for vertical fonts) |
| lsidebearing | number | (only if nonzero) |

```
glyph_class
                   number
                            (only if nonzero)
kerns
                            (only for horizontal fonts, if set)
                   array
vkerns
                            (only for vertical fonts, if set)
                   array
dependents
                   array
                            linear array of glyph name strings (only if nonempty)
                            (only if nonempty)
lookups
                   table
                   table
                            (only if nonempty)
ligatures
anchors
                   table
                            (only if set)
tex_height
                   number
                            (only if set)
                            (only if set)
tex_depth
                   number
tex_sub_pos
                   number
                            (only if set)
tex_super_pos number
                            (only if set)
comment
                   string
                            (only if set)
```

The kerns and vkerns are linear arrays of small hashes:

| key | type | explanation |
|--------|--------|-------------|
| char | string | |
| off | number | |
| lookup | string | |

The lookups is a hash based on lookup subtable names, with the value of each key inside that a linear array of small hashes:

| key | type | explanation |
|---------------|-------|--|
| type | enum | position, pair, substitution, alternate, multiple, ligature, |
| | | lcaret, kerning, vkerning, anchors, contextpos, contextsub, |
| | | chainpos, chainsub, reversesub, max, kernback, vkernback |
| specification | table | extra data |

For the first seven values of type, there can be additional sub-information, stored in the sub-table specification:

```
value
                type
                       explanation
position
                table
                      a table of the offset_specs type
pair
                table
                      one string: paired, and an array of one or two offset_specs tables: offsets
substitution table one string: variant
alternate
                table
                      one string: components
                table
                      one string: components
multiple
ligature
                table
                      two strings: components, char
lcaret
                array
                      linear array of numbers
```

Tables for offset_specs contain up to four number-valued fields: x (a horizontal offset), y (a vertical offset), h (an advance width correction) and v (an advance height correction).

The ligatures is a linear array of small hashes:

| key | type | explanation |
|-----|-------|--|
| lig | table | uses the same substructure as a single possub item |

```
strina
char
components array
                      linear array of named components
ccnt
              number
```

The anchor table is indexed by a string signifying the anchor type, which is one of

```
key
            type
                   explanation
mark
            table placement mark
basechar
            table
                   mark for attaching combining items to a base char
baselig
            table mark for attaching combining items to a ligature
                  generic mark for attaching combining items to connect to
basemark table
            table cursive entry point
centry
cexit
            table cursive exit point
```

The content of these is an short array of defined anchors, with the entry keys being the anchor names. For all except baselig, the value is a single table with this definition:

```
explanation
keu
                tupe
                number x location
Х
                number
                         y location
ttf_pt_index number truetype point index, only if given
```

For baselig, the value is a small array of such anchor sets sets, one for each constituent item of the ligature.

For clarification, an anchor table could for example look like this:

```
['anchor']={
  ['basemark']={
   ['Anchor-7'] = \{ ['x'] = 170, ['y'] = 1080 \}
  },
  ['mark']={
   ['Anchor-1'] = { ['x']=160, ['y']=810 },
   ['Anchor-4']= { ['x']=160, ['y']=800 }
  },
  ['baselig']={
   [1] = \{ ['Anchor-2'] = \{ ['x'] = 160, ['y'] = 650 \} \},
   [2] = \{ ['Anchor-2'] = \{ ['x'] = 460, ['y'] = 640 \} \}
  }
},
```

2 map table

The top-level map is a list of encoding mappings. Each of those is a table itself.

| key | type | explanation |
|----------|--------|---------------------------------------|
| enccount | number | |
| encmax | number | |
| backmax | number | |
| remap | table | |
| map | array | non-linear array of mappings |
| backmap | array | non-linear array of backward mappings |
| enc | table | |

The remap table is very small:

| key | type | explanation |
|----------|--------|-------------|
| firstenc | number | |
| lastenc | number | |
| infont | number | |

The enc table is a bit more verbose:

| key | type | explanation |
|-------------------------|--------|-----------------------------|
| enc_name | string | |
| char_cnt | number | |
| char_max | number | |
| unicode | array | of Unicode position numbers |
| psnames | array | of PosтScript glyph names |
| builtin | number | |
| hidden | number | |
| only_1byte | number | |
| has_1byte | number | |
| has_2byte | number | |
| $is_unicodebmp$ | number | (only if nonzero) |
| is_unicodefull | number | (only if nonzero) |
| is_custom | number | (only if nonzero) |
| is_original | number | (only if nonzero) |
| is_compact | number | (only if nonzero) |
| is_japanese | number | (only if nonzero) |
| is_korean | number | (only if nonzero) |
| ${\tt is_tradchinese}$ | number | (only if nonzero) |
| $is_simplechinese$ | number | (only if nonzero) |
| low_page | number | |
| high_page | number | |
| iconv_name | string | |
| iso_2022_escape | string | |

3 private table

This is the font's private PostScript dictionary, if any. Keys and values are both strings.

4 cidinfo table

| key | type | explanation |
|------------|--------|-------------|
| registry | string | |
| ordering | string | |
| supplement | number | |
| version | number | |

5 pfminfo table

The pfminfo table contains most of the OS/2 information:

| key | type | explanation |
|--------------------------|--------|-------------|
| pfmset | number | |
| winascent_add | number | |
| windescent_add | number | |
| hheadascent_add | number | |
| hheaddescent_add | number | |
| typoascent_add | number | |
| ${	t typodescent_add}$ | number | |
| subsuper_set | number | |
| panose_set | number | |
| hheadset | number | |
| vheadset | number | |
| pfmfamily | number | |
| weight | number | |
| width | number | |
| avgwidth | number | |
| firstchar | number | |
| lastchar | number | |
| fstype | number | |
| linegap | number | |
| vlinegap | number | |
| hhead_ascent | number | |
| hhead_descent | number | |
| hhead_descent | number | |
| os2_typoascent | number | |
| os2_typodescent | number | |
| ${\tt os2_typolinegap}$ | number | |
| os2_winascent | number | |
| os2_windescent | number | |

```
os2_subxsize
                   number
                   number
os2_subysize
os2_subxoff
                   number
os2_subyoff
                   number
os2_supxsize
                   number
os2_supysize
                   number
os2_supxoff
                   number
os2_supyoff
                   number
os2_strikeysize
                   number
os2_strikeypos
                   number
                   number
os2_family_class
os2_xheight
                   number
os2_capheight
                   number
os2_defaultchar
                   number
os2_breakchar
                   number
os2_vendor
                   string
                   table
panose
```

The panose subtable has exactly 10 string keys:

| key | type | explanation |
|-------------------------|--------|---|
| familytype | string | Values as in the OpenType font specification: Any, No Fit, Text and |
| | | Display, Script, Decorative, Pictorial |
| serifstyle | string | See the OpenType font specification for values |
| weight | string | id. |
| proportion | string | id. |
| contrast | string | id. |
| ${\tt strokevariation}$ | string | id. |
| armstyle | string | id. |
| letterform | string | id. |
| midline | string | id. |
| xheight | string | id. |

6 names table

Each item has two top-level keys:

```
key type explanationlang string language for this entrynames table
```

The names keys are the actual TRUETYPE name strings. The possible keys are:

```
key explanation copyright
```

family subfamily uniqueid fullname version postscriptname ${\tt trademark}$ manufacturerdesigner descriptor venderurl designerurl license licenseurl idontknow preffamilyname prefmodifiers compatfull sampletext cidfindfontname

7 anchor_classes table

The anchor_classes classes:

| key | type | explanation |
|--------|--------|---------------------------------------|
| name | string | A descriptive id of this anchor class |
| lookup | string | |
| tvpe | strina | One of 'mark', 'mkmk', 'curs', 'mkla' |

8 gpos table

Th gpos table has one array entry for each lookup.

| key | type | explanation |
|-----------|--------|--|
| type | string | One of 'gpos_single', 'gpos_pair', 'gpos_cursive', 'gpos_mark2base', 'gpos_mark2ligature', |
| | | 'gpos_mark2mark', 'gpos_context', 'gpos_contextchain' |
| flags | table | |
| name | string | |
| features | array | |
| subtables | array | |

The flags table has a true value for each of the lookup flags that is actually set:

key type explanation

r21 boolean ignorebaseglyphs boolean ignoreligatures boolean ignorecombiningmarks boolean

The features table has:

key type explanation
tag string
scripts table
ismax number (only if true)

The scripts table within features has:

key type explanation
script string

langs array of strings

The subtables table has:

| key | type | explanation |
|------------------|--------|----------------|
| name | string | |
| suffix | string | (only if used) |
| anchor_classes | number | (only if used) |
| vertical_kerning | number | (only if used) |
| kernclass | table | (only if used) |

The kernclass with subtables table has:

keytypeexplanationfirstsarray of stringssecondsarray of stringslookupstringassociated lookupoffsetsarray of numbers

9 gsub table

This has identical layout to the gpos table, except for the type:

10 ttf_tables table

| key | type | explanation |
|--------|--------|-------------|
| tag | string | |
| len | number | |
| maxlen | number | |
| data | number | |

11 kerns table

Substructure is identical to the per-glyph subtable.

12 vkerns table

Substructure is identical to the per-glyph subtable.

13 texdata table

| key | type | explanation | |
|--------|--------|----------------------------|--|
| type | string | unset, text, math, mathext | |
| params | arrau | 22 font numeric parameters | |

14 lookups table

Top-level lookups is quite different from the ones at character level. The keys in this hash are strings, the values the actual lookups, represented as dictionary tables.

| key | type | explanation |
|---------------|--------|---|
| type | number | |
| format | enum | One of 'glyphs', 'class', 'coverage', 'reversecoverage' |
| tag | string | |
| current_class | array | |
| before_class | array | |
| after_class | array | |
| rules | array | an array of rule items |
| | | |

Rule items have one common item and one specialized item:

| key | type | explanation |
|-----------------|-------|--|
| lookups | array | A linear array of lookup names |
| glyph | array | Only if the parent's format is 'glyph' |
| class | array | Only if the parent's format is 'glyph' |
| coverage | array | Only if the parent's format is 'glyph' |
| reversecoverage | array | Only if the parent's format is 'glyph' |

A glyph table is:

```
key type explanation names string back string fore string
```

A class table is:

```
keytypeexplanationcurrentarrayof numbersbeforearrayof numbersafterarrayof numbers
```

coverage:

| key | type | explanation |
|---------|-------|-------------|
| current | array | of strings |
| before | array | of strings |
| after | array | of strings |

reversecoverage:

| key | type | explanation |
|--------------|--------|-------------|
| current | array | of strings |
| before | array | of strings |
| after | array | of strings |
| replacements | string | |

4.14 The lang library

This library provides the interface to LuATEX's structure representing a language, and the associated functions.

```
<language> 1 = lang.new()
<language> 1 = lang.new(number id)
```

This function creates a new userdata object. An object of type <language> is the first argument to most of the other functions in the lang library. These functions can also be used as if they were object methods, using the colon syntax.

Without an argument, the next available internal id number will be assigned to this object. With argument, an object will be created that links to the internal language with that id number.

```
number n = lang.id(<language> 1)
```

returns the internal \language id number this object refers to.

```
string n = lang.hyphenation(<language> 1)
lang.hyphenation(<language> 1, string n)
```

Either returns the current hyphenation exceptions for this language, or adds new ones. The syntax of the string is explained in the next chapter, section 5.3.

```
lang.clear_hyphenation(<language> 1)
```

Clears the exception dictionary for this language.

```
string n = lang.clean(string o)
```

Creates a hypenation key from the supplied hyphenation value. The syntax of the argument string is explained in the next chapter, section 5.3. This function is useful if you want to do something else based on the words in a dictionary file, like spell-checking.

```
string n = lang.patterns(<language> 1)
lang.patterns(<language> 1, string n)
```

Adds additional patterns for this language object, or returns the current set. The syntax of this string is explained in the next chapter, section 5.3.

```
lang.clear_patterns(<language> 1)
```

Clears the pattern dictionary for this language.

```
number n = lang.prehyphenchar(<language> 1)
lang.prehyphenchar(<language> 1, number n)
```

Gets or sets the 'pre-break' hyphen character for this font (initially the hyphen, decimal 45).

```
number n = lang.posthyphenchar(<language> 1)
lang.posthyphenchar(<language> 1, number n)
```

Gets or sets the 'post-break' hyphen character for this font (initially null, decimal 0).

```
<node> head, boolean succes = lang.hyphenate(<node> head)
<node> head, boolean succes = lang.hyphenate(<node> head, <node> tail)
```

Inserts hyphenation points (discretionary nodes) in a node list. If tail is given as argument, processings stops on that node. Currently, succes is always true if head and tail are proper nodes, regardless of possible other errors.

5 Languages and characters, Fonts and glyphs

LUATEX's internal handling of the characters and glyphs that eventually become typeset is quite different from the way TEX82 handles those same objects. The easiest way to explain the difference is to focus on unrestricted horizontal mode (i.e. paragraphs) and hyphenation first. Later on, it will be easy to deal with the differences that occur in horizontal and math modes.

In TEX82, the characters you type are converted into char_node record when they are encountered by the main control loop. TEX attaches and processes the font information while creating those records, so that the resulting 'horizontal list' contains the final forms of ligatures and implicit kerning.

When it becomes necessary to hyphenate words in a paragraph, TEX converts the char_node records into a string one word at time (by replacing ligatures with their components and ignoring the kerning), runs the hyphenation algorithm on this string, and converts the hyphenated result back into a 'horizontal list' that is then spliced back into the main paragraph stream.

The char_node records are somewhat misnamed, as they are glyph posisitions in specific fonts, and therefore not really 'characters' in the linguistic sense. There is no language information inside the char_node records. Instead, language information is passed along using language whatsit records inside the horizontal list.

IN LuaTEX, the situation is quite different. The characters you type are always converted into glyph_node records with a special subtype representing the fact that they are intended to be linguistic characters. LuaTEX stores the needed language information in those records, but does not do any font-related processing yet.

When it becomes necessary to typeset a paragraph, LuaTEX first inserts all hyphenation points into the whole horizontal list. Next it processes all the font information in the whole list (creating ligatures and kerning), and finally it adjusts all the subtype identifiers so that the records are 'glyph nodes' from now on.

That was the broad overview. The rest of this chapter will deal with the minutiae of the new process.

5.1 Characters and glyphs

TEX82 (including PDFTEX) differentiates between char_nodes and lig_nodes. The former are simple items that contained nothing but a 'character' and a 'font' field, and they lived in the same memory are as tokens. The latter also contained a list of components, and a subtype indicating whether this ligature was the result of a word boundary, and it was stored in the same place as other nodes like boxes and kerns and glues.

In LuaTEX, these two types are merged into one, somewhat larger structure called a glyph_node. Besides having the old character, font, and component fields, and the new special fields like 'attr' (see section 7.1.2.12), these nodes also contain:

• A subtype, split into four main types:

- 'character' -- for characters to be hyphenated
- 'qlyph' -- for specific font qlyphs
- 'ligature' -- for ligatures
- 'ghost' -- for 'ghost objects'

The latter two make further use of two extra fields:

- 'left' -- for ligatures: created from a left word boundary, for ghosts: created from \leftghost
- 'right' -- for ligatures: created from a right word boundary. for ghosts: created from \rightghost

for ligatures, both bits can be set at the same time (in case of a single-glyph word).

glyph nodes of type 'character' also contain language data, split into four items that were current when the node was created: the \setlanguage (15 bits), \lefthyphenmin (8 bits), \righthyphenmin (8 bits), and \uchyph (1 bit).

Incidentally, LuATFX allows 32768 separate languages, and words can be 256 characters long.

Because the \uchyph value is saved in the actual nodes, its handling is subtly different from TFX82: changes to \uchyph become effective immediately, not at the end of the current partial paragraph.

Typeset boxes now always have their language information embedded in the nodes themselves, so there is no longer a possible dependancy on the surrounding language settings. In TFX82, a mid-paragraph statement like \unhbox0 would process the box using the current paragraph language unless there was a \setlanguage issued inside the box. In LuATFX, all language variables are already frozen.

The main control loop

In LuaTFX's main loop, almost all input characters that are to be typeset are converted into glyph node records with subtype 'character', but there are a few small exceptions.

First, the \accent primitives creates nodes with subtype 'qlyph' instead of 'character': one for the actual accent and one for the accentee. The primary reason for this is that \accent in TFX82 is explicitly dependant on the current font encoding, so it would not make much sense to attach a new meaning to the primitive's name, as that would invalidate many old documents and macro packages. A secondary reason is that in TFX82, \accent prohibits hyphenation of the current word. Since in LuATFX hyphenation only takes place on 'character' nodes, it is possible to achieve the same effect.

This change of meaning did happen with \char, that now generates 'character' nodes, consistent with it's changed meaning in $X \exists T \in X$. The changed status of \c is not yet finalized, but if it stays as it is now, a new primitive \glyph should be added to directly insert a font glyph id.

Second, all the results of processing in math mode eventually become nodes with 'glyph' subtypes.

Third, the Aleph-derived commands \leftghost and \rightghost create nodes of a third subtype: 'qhost'. These nodes are ignored completely by all further processing until the stage where inter-glyph kerning is added.

Fourth, automatic discretionaries are handled differently. TFX82 inserts an empty discretionary after sensing an input character that matches the \hyphenchar in the current font. This test is wrong, in our

opinion: wether or not hyphenation takes place should not depend on the current font, it is a language property.

In LuaTFX, it works like this: if LuaTFX senses an input character that matches the value of the new integer parameter \exhyphenchar, it will insert an automatic discretionary with the current language's \prehyphenchar in the pre-break text (if it is non-zero, otherwise the pre-break text will be empty), the current language's \posthyphenchar in the post-break (also only if it is non-zero), and the actual input character in the no-break text.

Initex sets the \exhyphenchar=`\-, and all languages start out with \prehyphenchar=`\- and \posthyphenchar=0. When you assign the values of \prehyphenchar and \posthyphenchar, you are actually changing the settings for the current \language, this behaviour is compatible with \patterns and \hyphenation.

The exact status and meaning of \hyphenchar is still under consideration, it will probably become used in the character to glyph conversion stage. Currently, it is simply ignored.

Fifth, \setlanguage no longer creates whatsits. The meaning of \setlanguage is changed so that it is now an integer parameter like all others. That integer parameter is used in \glyph_node creation to add language information to the glyph nodes. In conjunction, the \language primitive is extended so that it always also updates the value of \setlanguage.

Sixth, the \noboundary command (this command prohibits word boundary processing where that would normally take place) now does create whatsits. These whatsits are needed because the exact place of the \noboundary command in the input stream has to be retained until after the ligature and font processing stages.

Finally, there is no longer a main_loop label in the code. Remember that TFX82 did quite a lot of processing while adding char_nodes to the horizontal list? For speed reasons, it handled that processing code outside of the 'main control' loop, and only the first character of any 'word' was handled by that 'main control' loop. In LUATFX, there is no longer a need for that (all hard work is done later), and the (now very small) bits of character-handling code have been moved back inline. When \tracingcommands is on, this is visible because the full word is reported, instead of just the initial character.

Loading patterns and exceptions

The hyphenation algorithm in LuATFX is quite different from the one in TFX82, although it uses essentially the same user input.

After expansion, the argument for \patterns has to be proper UTF-8, no \char or \chardef-ed commands are allowed. (The current implementation is even more strict, and will reject all non-unicode characters, but that will be changed in the future. For now, the generated errors are a valuable tool in discovering font-encoding specific pattern files)

Likewise, the expanded argument for \hyphenation also has to be proper UTF-8, but here a tiny little bit of extra syntax is provided:

- 1. three sets of arguments in curly braces $(\{\}\{\}\{\})$ indicates a desired complex discretionary, with arguments as in \discretionary's command in normal document input.
- 2. indicates a desired simple discretionary, cf. \- and \discretionary{-}{}} in normal document input.
- 3. Internal command names are ignored. This rule is provided especially for \discretionary, but it also helps deal with \relax commands that may sneak in.
- 4. = indicates a hyphen in the document input (but that is only useful in documents where \exhyphenchar is not equal to the hyphen).

The expanded argument is first converted back to a space-separated string while dropping the internal command names. This string is then converted into a dictionary by a routine that creates key-value pairs by converting the other listed items. It is important to note that the keys in an exception dictionary can always be generated from the values. Here are a few examples:

```
value
                  implied key (input)
                                    effect
                                    ta\-ble (= ta\discretionary {-}{}{}ble)
ta-ble
ba\{k-\}\{\}\{c\}ken backen
                                    ba\discretionary {k-}{}{c}ken
```

The resultant patterns and exception dictionary will be stored under the language code that is the present value of \language.

In the last line of the table, you see there is no \discretionary command in the value: the command is optional in the TFX-based input syntax. The underlying reason for that is that it is conceivable that a whole dictionary of words is stored as a plain text file and loaded into LUATEX using one of the functions in the Lua lang library. This loading method is quite a bit faster than going through the TFX language primitives, but some (most?) of that speed gain would be lost if it had to interpret command sequences while doing so.

The motivation behind the ε -TEX extension \savinghyphcodes was that hyphenation heavily depended on font encodings. This is no longer true in LuATFX, and the corresponding primitive is ignored pending complete removal. The future semantics of \uppercase and \lowercase are still under consideration, no changes have taken place yet.

5.4 Applying hyphenation

The internal structures LUATEX uses for the insertion of discretionaries in words is very different from the ones in TFX82, and that means there are some noticable differences in handling as well.

First and foremost, there is no 'compressed trie' involved (LuATFX uses a finite state hash, an idea based on the 'libhnj' library that is used by OpenOffice). Differences between LUATEX and TEX82 that are a direct result of that:

- LUATEX happily hyphenates the full Unicode character range.
- Pattern and exception dictionary size is limited by the available memory only, all allocations are done dynamically. The trie-related settings in texmf.cnf are ignored.

- Because there is no 'trie preparation' stage, language patterns never become frozen. This means
 that the primitive \patterns (and it's lua counterpart lang.patterns) can be used at any time,
 not only in initex.
- Only the string representation of \patterns and \hyphenation is stored in the format file. At format load time, they are simply re-evaluated. It follows that there is no real reason to preload languages in the format file. In fact, it is usually not a good idea to do so. It is much smarter to load patterns no sooner than the first time they are actually needed.

Previously, there were problems with changing the node attributes mid-word, but that problem is now solved, as nodes in a word are not converted to and from a string any more (this was required by the old hyphenation code), they are editted in place. Inserted characters and ligatures inherit their attributes from the nearest glyph node item (usually the preceding one, but the following one for the items inserted at the left-hand side of a word).

Word boundaries are no longer implied by font switches, but by language switches. One word can have two separate fonts and still be hyphenated correctly (but it can not have two different languages, the \setlanguage command forces a word boundary).

LUATEX also hyphenates the first word in a paragraph.

Words can be up to 256 characters long (up from 64 in T_EX82). Longer words generate an error right now, but eventually either the limitation will be removed or perhaps it will become possible to silently ignore the excess characters (this is what happens in T_EX82, but there the behaviour cannot be controlled).

If you are using the Lua function lang.hyphenate, you should be aware that this function expects to receive a list of 'character' nodes. It will not operate properly in the presence of 'glyph', 'ligature', or 'ghost' nodes, nor does it know how to deal with kerning. In the near future, it will be able to skip over 'ghost' nodes, and we may add a less fuzzy function you can call as well.

5.5 Applying ligatures and kerning

After all possible hyphenation points have been inserted in the list, LuaTEX will process the list to convert the 'character' nodes into 'glyph' and 'ligature' nodes. This is actually done in two stages: first all ligatures are processed, then all kerning information is applied to the result list. But those two stages are somewhat dependant on each other: If the used font makes it possible to do so, the ligaturing stage adds virtual 'character' nodes to the word boundaries in the list. While doing so, it removes and interprets noboundary nodes. The kerning stage deletes those word boundary items after it is done with them, and it does the same for 'ghost' nodes. Finally, at the end of the kerning stage, all remaining 'character' nodes are converted to 'glyph' nodes.

This work separation is worth mentioning because, if you overrule from Lua only one of the two callbacks related to font handling, then you have to make sure you perform the tasks normally done by LUATEX itself in order to make sure that the other, non-overrruled, routine continues to function properly.

Work in this area is not yet complete, but most of the possible cases are handled by our rewritten ligaturing engine. We are working hard to make sure all of the possible inputs will become supported soon.

For example, take the word office, hyphenated of-fice, using a 'normal' font with all the f-i ligatures:

Initial: ${o}{f}{i}{c}{e}$

After hyphenation: $\{0\}\{f\}\{\{-\}, \{\}, \{\}\}\{i\}\{c\}\{e\}\}$ First ligature stage: $\{0\}\{\{f\}\{-\}, \{ff\}, \{ff\}\}\{i\}\{c\}\{e\}\}$ Final result: $\{0\}\{\{f\}\{-\}, \{fi\}, \{ffi\}\}\{c\}\{e\}$

That's bad enough, but if there was a hyphenation point between the f and the i: of-f-ice, the final result should be:

```
{o}{{f}{-},
    {{f}}{-},
    {i},
    {fi}},
    {ffi}},
    {{ff}}{-},
    {iff}{-},
    {iff}}-
```

with discretionaries in the post-break text as well as in the replacement text of the top-level discretionary that resulted from the first hyphenation point. And this is only a simple case.

5.6 Breaking paragraphs into lines

This code is still almost unchanged, but because of the above-mentioned changes with respect to discretionaries and ligatures, line breaking will potentially be different from traditional TEX. The actual line breaking code is still based on the TEX82 algoritms, and it does not expect there to be discretionaries inside of discretionaries.

But that situation is now fairly common in LuATEX, due to the changes to the ligaturing mechanism. And also, the LuATEX discretionary nodes are implemented slightly different from the TEX82 nodes: the no_break text is now embedded inside the disc node where previously, these nodes kept their place in the horizontal list (the discretionary node contained a counter indicating how many nodes to skip).

The combined effect of these two differences is that LuaTEX does not always use all of the potential breakpoints in a paragraph, especially when fonts with many ligatures are used.

6 Font structure

All TEX fonts are represented to LUA code as tables, and internally as C structures. All keys in the table below are saved in the internal font structure if they are present in the table returned by the define_font callback, or if they result from the normal TFM/VF reading routines if there is no define font callback defined.

The column 'from vF' means that this key will be created by the font.read_vf() routine, 'from TFM' means that the key will be created by the font.read_tfm() routine, and 'used' means whether or not the LUATEX engine itself will do something with the key.

The top-level keys in the table are as follows:

| key | from vf | from tfm | used | value type | description |
|---------------|---------|----------|------|------------|---|
| name | yes | yes | yes | string | metric (file) name |
| area | no | yes | yes | string | (directory)location, typically empty |
| used | no | yes | yes | boolean | used already? (initial: false) |
| characters | yes | yes | yes | table | the defined glyphs of this font |
| checksum | yes | yes | no | number | default: 0 |
| designsize | no | yes | yes | number | expected size (default: $655360 == 10pt$) |
| direction | no | yes | yes | number | default: 0 (LTR) |
| encodingbytes | no | no | yes | number | default: depends on format |
| encodingname | no | no | yes | string | encoding name |
| fonts | yes | no | yes | table | locally used fonts |
| fullname | no | no | yes | string | actual (PostScript) name |
| header | yes | no | no | string | header comments, if any |
| hyphenchar | no | no | yes | number | default: TeX's \hyphenchar |
| parameters | no | yes | yes | hash | default: 7 parameters, all zero |
| size | no | yes | yes | number | loaded (at) size. (default: same as designsize) |
| skewchar | no | no | yes | number | default: TeX's \skewchar |
| type | yes | no | yes | string | basic type of this font |
| format | no | no | yes | string | disk format type |
| embedding | no | no | yes | string | PDF inclusion |
| filename | no | no | yes | string | disk file name |
| tounicode | no | yes | yes | number | if 1, LuaTEX assumes per-glyph tounicode en- |
| | | | | | tries are present in the font |

The key name is always required.

The key used is set by the engine when a font is actively in use, this makes sure that the font's definition is written to the output file (DVI or PDF). The TFM reader sets it to false.

The direction is a number signalling the 'normal' direction for this font. There are sixteen possibilities:

| number | meaning | number | meaning |
|--------|---------|--------|---------|
| 0 | LT | 8 | TT |

| 1 | LL | 9 | TL |
|---|----|----|----|
| 2 | LB | 10 | TB |
| 3 | LR | 11 | TR |
| 4 | RT | 12 | BT |
| 5 | RL | 13 | BL |
| 6 | RB | 14 | BB |
| 7 | RR | 15 | BR |

These are Omega-style direction abbreviations: the first character indicates the 'first' edge of the character glyphs (the edge that is seen first in the writing direction), the second the 'top' side.

The parameters is a hash with mixed key types. There are seven possible string keys, as well as a number of integer indices (these start from 8 up). The seven strings are actually used instead of the bottom seven indices, because that gives a nicer user interface.

The names and their internal remapping:

| name | internal remapped number |
|---------------|--------------------------|
| slant | 1 |
| space | 2 |
| space_stretch | 3 |
| space_shrink | 4 |
| x_height | 5 |
| quad | 6 |
| extra_space | 7 |

The keys type, format, embedding, fullname and filename are used to embed OpenType fonts in the result PDF.

The characters table is a list of character hashes indexed by integer number. The number is the 'internal code' TEX knows this character by.

Two very special string indexes can be used also: left_boundary is a virtual character whose ligatures and kerns are used to handle word boundary processing. right_boundary is similar but not actually used for anything (yet!).

Other index keys are ignored.

Each character hash itself is a hash. For example, here is the character 'f' (decimal 102) in the font cmr10 at 10 points:

```
[102] = {
  ['width'] = 200250
  ['height'] = 455111,
  ['depth'] = 0,
  ['italic'] = 50973,
  ['kerns'] = {
     [63] = 50973,
     [93] = 50973,
```

```
[39] = 50973,
     [33] = 50973,
     [41] = 50973
  },
  ['ligatures'] = {
    [102] = {
       ['char'] = 11,
       ['type'] = 0
    },
    [108] = {
       ['char'] = 13,
       ['type'] = 0
    },
    [105] = {
       ['char'] = 12,
       ['type'] = 0
    }
  },
}
```

The following top-level keys can be present inside a character hash:

| key | from vf | from tfm | used | value type | description |
|------------|---------|----------|-------|------------|---|
| width | yes | yes | yes | number | character's width, in sp (default 0) |
| height | no | yes | yes | number | character's height, in sp (default 0) |
| depth | no | yes | yes | number | character's depth, in sp (default 0) |
| italic | no | yes | yes | number | character's italic correction, in sp (default zero) |
| tounicode | no | no | maybe | string | character's Unicode equivalent(s), in UTF-16BE |
| | | | | | hexadecimal format |
| next | no | yes | yes | number | the 'next larger' character index |
| extensible | no | yes | yes | table | the constituent parts of an extensible recipe |
| kerns | no | yes | yes | table | kerning information |
| ligatures | no | yes | yes | table | ligaturing information |
| commands | yes | no | yes | array | virtual font commands |
| name | no | no | no | string | the character (PostScript) name |
| index | no | no | yes | number | the (OpenType or TrueType) font glyph index |
| used | no | yes | yes | boolean | typeset already (default: false)? |

The usage of tounicode is this: if this font specifies a tounicode=1 at the top level, then LuaTEX will construct a /ToUnicode entry for the PDF font (or font subset) based on the character-level tounicode strings, where they are available. If a character does not have a sensible Unicode equivalent, do not provide a string either (no empty strings).

If the font-level tounicode is not set, then LuaTEX will build up /ToUnicode based on the TEX code points you used, and any character-level tounicodes will be ignored. At the moment, the string format is exactly the format that is expected by Adobe CMAP files (UTF-16BE in hexadecimal encoding), minus the enclosing angle brackets. This may change in the future.. Small example: the tounicode for a fi ligature would be 00660069.

The presence of extensible will overrule next, if that is also present.

The extensible table is very simple:

```
key type description
top number 'top' character index
mid number 'middle' character index
bot number 'bottom' character index
rep number 'repeatable' character index
```

The kerns table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right_boundary), with the values the kerning to be applied, in scaled points.

The ligatures table is a hash indexed by character index (and 'character index' is defined as either a non-negative integer or the string value right_boundary), with the values being yet another small hash, with two fields:

```
key type descriptiontype number the type of this ligature command, default 0char number the character index of the resultant ligature
```

The **char** field in a ligature is required.

The type field inside a ligature is the numerical or string value of one of the eight possible ligature types supported by TEX. When TEX inserts a new ligature, it puts the new glyph in the middle of the left and right glyphs. The original left and right glyphs can optionally be retained, and when at least one of them is kept, it is also possible to move the new 'insertion point' forward one or two places. The glyph that ends up to the right of the insertion point will become the next 'left'.

| textual (Knuth) | number | string | result |
|-------------------|--------|--------|--------|
| l + r =: n | 0 | =: | n |
| $l + r =: \mid n$ | 1 | =: | nr |
| l + r =: n | 2 | =: | ln |
| l + r = n | 3 | =: | lnr |
| l + r =: > n | 5 | =: > | n r |
| l + r = > n | 6 | =:> | l n |
| l + r = > n | 7 | =: > | l nr |
| l + r = > n | 11 | =: >> | ln r |

The default value is 0, and can be left out. That signifies a 'normal' ligature where the ligature replaces both original glyphs. In this table the | indicates the final insertion point.

The commands array is explained below.

6.1 Real fonts

Whether or not a TEX font is a 'real' font that should be written to the PDF document is decided by the type value in the top-level font structure. If the value is real, then this is a proper font, and the inclusion mechanism will attempt to add the needed font object definitions to the PDF.

Values for type:

value description real this is a base font virtual this is a virtual font

The actions to be taken depend on a number of different variables:

- Whether the used font fits in an 8-bit encoding scheme or not
- The type of the disk font file
- The level of embedding requested

A font that uses anything other than an 8-bit encoding vector has to be written to the PDF in a different way.

The rule is: if the font table has encodingbytes set to 2, then this is a wide font, in all other cases it isn't. The value 2 is the default for OpenType and TrueType fonts loaded via Lua. For Type1 fonts, you have to set encodingbytes to 2 explicitly. For PK bitmap fonts, wide font encoding is not supported at all.

If no special care is needed, LuaTEX currently falls back to the mapfile-based solution used by PDFTEX and DVIPS. This behaviour will be removed in the future, when the existing code becomes integrated in the new subsystem.

But if this is a 'wide' font, then the new subsystem kicks in, and some extra fields have to be present in the font structure. In this case, LuaT_EX does not use a map file at all.

The extra fields are: format, embedding, fullname, cidinfo (as explained above), filename, and the index key in the separate characters.

Values for format are:

| value | description |
|----------|--|
| type1 | this is a PostScript Type1 font |
| type3 | this is a bitmapped (PK) font |
| truetype | this is a TrueType or TrueType-based OpenType font |
| opentype | this is a PostScript-based OpenType font |

(type3 fonts are provided for backward compatibility only, and do not support the new wide encoding options.)

Values for embedding are:

value description

no don't embed the font at all

subset include and atttempt to subset the font

full include this font in it's entirety

It is not possible to artificially modify the transformation matrix for the font at the moment.

The other fields are used as follows: The fullname will be the PostScript/PDF font name. The cidinfo will be used as the character set (the CID /Ordering and /Registry keys). The filename points to the actual font file. If you include the full path in the filename or if the file is in the local directory, LuaTeX will run a little bit more efficient because it will not have to re-run the find_xxx_file callback in that case.

Be careful: when mixing old and new fonts in one document, it is possible to create PostScript name clashes that can result in printing errors. When this happens, you have to change the fullname of the font.

Typeset strings are written out in a wide format using 2 bytes per glyph, using the index key in the character information as value. The overall effect is like having an encoding based on numbers instead of traditional (PostScript) name-based reencoding. The way to get the correct index numbers for Type1 fonts is by loading the font via fontforge.open; use the table indices as index fields.

This type of reencoding means that there is no longer a clear connection between the text in your input file and the strings in the output PDF file. Dealing with this is high on the agenda.

6.2 Virtual fonts

You have to take the following steps if you want LUATEX to treat the returned table from define_font as a virtual font:

- Set the top-level key type to virtual.
- Make sure there is at least one valid entry in fonts (see below)
- Give a commands array to every character (see below)

The presence of the toplevel type key with the specific value virtual will trigger handling of the rest of the special virtual font fields in the table, but the mere existence of 'type' is enough to prevent LUATEX from looking for a virtual font on its own.

Therefore, this also works 'in reverse': if you are absolutely certain that a font is not a virtual font, assigning the value base or real to type will inhibit LUATEX from looking for a virtual font file, thereby saving you a disk search.

The fonts is another Lua array. The values are one- or two-key hashes themselves, each entry indicating one of the base fonts in a virtual font. An example makes this easy to understand

says that the first referenced font (index 1) in this virtual font is ptrmr8a loaded at 10pt, and the second is psyr loaded at a little over 9pt. The third one is previously defined font that is known to LUATEX as fontid '38'.

The array index numbers are used by the character command definitions that are part of each character.

The commands array is a hash here each item is another small array, with first entry representing a command and the extra items the parameters to that command. The allowed commands and their arguments are:

| command name | arguments | arg type | description |
|--------------|-----------|-----------|--|
| font | 1 | number | select a new font from the local fonts table |
| char | 1 | number | typeset this character number from the current |
| node | 1 | node | output this node (list), and move right |
| slot | 2 | number | a shortcut for a font, char set |
| push | 0 | | save current position |
| nop | 0 | | do nothing |
| pop | 0 | | pop position |
| rule | 2 | 2 numbers | output a rule $w * h$, and move right |
| down | 1 | number | move down on the page |
| right | 1 | number | move right on the page |
| special | 1 | string | output a \special command |
| comment | any | any | the rest of the command is ignored |

Here is a rather elaborate glyph commands example:

```
commands = {
 {'push'},
                                -- remember where we are
  {'right', 5000},
                                -- move right about 0.08pt
 {'font', 1},
                                -- select the fonts[1] entry
 {'char', 97},
                                -- place character 97 (a)
 {'pop'},
                                -- go all the way back
 {'down', -200000},
                                -- move *up* about 3pt
 {'special', 'pdf: 1 0 0 rg'}
                                -- switch to red color
 {'rule', 500000, 20000}
                                -- draw a bar
 {'special','pdf: 0 g'}
                                -- back to black
}
```

The default value for font is always 1, for each character anew. If the virtual font is essentially only a re-encoding, then you do usually not have create an explicit 'font' entry.

Regardless of the amount of movement you create within the commands, the output pointer will always move by exactly the width as given in the width key of the character hash, after running the commands.

6.2.1 Artificial fonts

Even in a 'real' font, there can be virtual characters. When LuATFX encounters a commands field inside a character when it becomes time to typeset the character, it will interpret the commands, just like for a true virtual character. In this case, if you have created no 'fonts' array, then the default and only 'base' font is taken to be the current font itself. In practise, this means that you can create virtual duplicates of existing characters.

Note: this feature does not work the other way around. There can not be 'real' characters in a virtual font!

Finally, here is a plain TEX input file with a virtual font demonstration:

```
\directlua0 {
 callback.register('define_font',
    function (name, size)
      if name == 'cmr10-red' then
        f = font.read_tfm('cmr10',size)
        f.name = 'cmr10-red'
        f.type = 'virtual'
        f.fonts = {{ name = 'cmr10', size = size }}
        for i,v in pairs(f.characters) do
          if (string.char(i)):find('[tacohanshartmut]') then
             v.commands = {
               {'special','pdf: 1 0 0 rg'},
               {'char',i},
               {'special','pdf: 0 g'},
          else
             v.commands = {{'char',i}}
          end
        end
      else
        f = font.read_tfm(name,size)
      end
      return f
    end
  )
}
```

7 Nodes

7.1 LUA node representation

TEX's nodes are represented in LuA as userdata object with a variable set of fields. In the following syntax tables, such the type of such a userdata object is represented as $\langle node \rangle$.

The current return value of node.types() is: vlist (1), rule (2), ins (3), mark (4), adjust (5), disc (7), whatsit (8), math (9), glue (10), kern (11), penalty (12), unset (13), style (14), choice (15), ord (16), op (17), bin (18), rel (19), open (20), close (21), punct (22), inner (23), radical (24), fraction (25), under (26), over (27), accent (28), vcenter (29), left (30), right (31), action (39), margin_kern (40), glyph (41), attribute (42), glue_spec (43), attribute_list (44), hlist (0), but as already mentioned, the math and alignment nodes in this list are not supported at the moment. The useful list is described in the next sections.

7.1.1 Auxiliary items

A few node-typed userdata objects do not occur in the 'normal' list of nodes, but can be pointed to from within that list. They are not quite the same as regular nodes, but it is easier for the library routines to treat them as if they were.

7.1.1.1 qlue_spec items

Skips are about the only type of data objects in traditional TEX that are not a simple value. The structure that represents the glue components of a skip is called a glue_spec, and it has the following accessible fields:

| key | type | explanation |
|---------------|--------|-------------|
| width | number | |
| stretch | number | |
| stretch_order | number | |
| shrink | number | |
| shrink_order | number | |

These objects are reference counted, so there is actually an extra field named ref_count as well. This item type will likely disappear in the near future, and the glue fields themselves will become part of the nodes referencing glue items.

7.1.1.2 attribute_list items

The newly introduced attribute registers are non-trivial, because the value that is attached to a node is essentially a sparse array of key-value pairs.

It is generally easiest to deal with attributes by using the dedicated functions in the **node** library, but for completeness, here is the low-level interface:

```
field type explanation
next <node> pointer to the first attribute
```

There are no extra fields, this kind of item is only used as a head pointer for attribute items, making them easier to handle.

A normal node's attribute field will point to an item of type attribute_list, and the next field in that item will point to the first defined 'attribute' item, whose next will point to the second 'attribute' item, etc.

7.1.1.3 attribute item

Valid fields:

| field | type | explanation |
|--------|---------------|-------------------------------|
| next | <node></node> | pointer to the next attribute |
| number | number | the attribute type id |
| value | number | the attribute value |

7.1.1.4 action item

Valid fields: action_type, named_id, action_id, file, new_window, data, ref_count These are a special kind of item that only appears inside pdf start link objects.

| field | type | explanation |
|-------------------|------------------|-------------|
| action_type | number | |
| action_id | number or string | |
| ${\tt named_id}$ | number | |
| file | string | |
| new_window | number | |
| data | string | |
| ref_count | number | |

7.1.2 Main text nodes

These are the nodes that comprise actual typesetting commands.

A few fields are present in all nodes regardless of their type, these are:

```
field type explanation
next <node> The next node in a list, or nil
```

```
id number The node's type (id) number subtype number The node subtype identifier
```

The subtype is sometimes just a stub entry. Not all nodes actually use the subtype, but this way you can be sure that all nodes accept it as a valid field name, and that is often handy in node list traversal. In the following tables next and id are not explicitly mentioned.

Besides these three fields, almost all nodes also have an attr field, and there is a also field called prev. That last field is always present, but only initialized on explicit request: when the function node.slide() is called, it will set up the prev fields to be a backwards pointer in the argument node list.

7.1.2.1 hlist nodes

Valid fields: attr, width, depth, height, dir, shift, glue_order, glue_sign, glue_set, list

| field | type | explanation |
|------------|---------------|---|
| subtype | number | unused |
| attr | <node></node> | The head of the associated attribute list |
| width | number | |
| height | number | |
| depth | number | |
| shift | number | a displacement perpendicular to the character progression direction |
| glue_order | number | a number in the range 04, indicating the glue order |
| glue_set | number | the calculated glue ratio |
| glue_sign | number | |
| list | <node></node> | the body of this list |
| dir | number | the direction of this box |

7.1.2.2 vlist nodes

Valid fields: As for hlist, except that 'shift' is a displacement perpendicular to the line progression direction.

7.1.2.3 rule nodes

Valid fields: attr, width, depth, height, dir

| field | type | explanation |
|---------|---------------|--|
| subtype | number | unused |
| attr | <node></node> | |
| width | number | rule size. The special value -1073741824 is used for 'running' glue dimensions |
| height | number | |
| depth | number | 11 |
| dir | number | the direction of this rule |

7.1.2.4 ins nodes

Valid fields: attr, cost, depth, height, top_skip, list

| field | type | explanation |
|----------|---------------|--|
| subtype | number | the insertion class |
| attr | <node></node> | |
| cost | number | the penalty associated with this insert |
| height | number | |
| depth | number | |
| list | <node></node> | the body of this insert |
| top_skip | <node></node> | a pointer to the \splittopskip glue spec |

7.1.2.5 mark nodes

Valid fields: attr, class, mark

| field | type | explanation |
|---------|---------------|-----------------------------------|
| subtype | number | unused |
| attr | <node></node> | |
| class | number | the mark class |
| mark | table | a table representing a token list |

7.1.2.6 adjust nodes

Valid fields: attr, list

| field | type | explanation |
|---------|---------------|-----------------------|
| subtype | number | 0 = normal, 1 = 'pre' |
| attr | <node></node> | |
| list | <node></node> | adiusted material |

7.1.2.7 disc nodes

Valid fields: attr, pre, post, replace

| field | type | explanation |
|---------|---------------|--------------------------------|
| subtype | number | unused |
| attr | <node></node> | |
| pre | <node></node> | pointer to the pre-break text |
| post | <node></node> | pointer to the post-break text |
| replace | <node></node> | pointer to the no-break text |

7.1.2.8 math nodes

Valid fields: attr, surround

field type explanation
subtype number 0 = 'on', 1 = 'off'
attr <node>
surround number width of the \mathsurround kern

7.1.2.9 glue nodes

Valid fields: attr, spec, leader

7.1.2.10 kern nodes

Valid fields: attr, kern

field type explanation subtype number $0 = \text{from font}, 1 = \text{from } \text{ or } \ \ 2 = \text{from } \text{ accent attr}$ <node> kern number

7.1.2.11 penalty nodes

Valid fields: attr, penalty

field type explanation
subtype number not used
attr <node>
penalty number

7.1.2.12 glyph nodes

Valid fields: attr, char, font, lang, left, right, uchyph, components, xoffset, yoffset

| field subtype | type number | explanation bitfield, with bits: |
|---------------------------------------|--|---|
| | | 0 character1 glyph2 ligature3 ghost4 left5 right |
| attr char font lang left right uchyph | <node> number number number number number boolean</node> | |
| components xoffset yoffset | <node> number number</node> | pointer to ligature components |

7.1.2.13 margin_kern nodes

Valid fields: attr, width, glyph

| field | type | explanation |
|---------|---------------|-------------------------------|
| subtype | number | 0 = left side, 1 = right side |
| attr | <node></node> | |
| width | number | |
| glyph | <node></node> | |

7.1.3 whatsit nodes

Whatsit nodes come in many subtypes, that you can ask for my running node.whatsits(): write (1), close (2), special (3), language (4), local_par (6), dir (7), pdf_literal (8), pdf_refobj (10), pdf_refxform (12), pdf_refximage (14), pdf_annot (15), pdf_start_link (16), pdf_end_link (17), pdf_dest (19), pdf_thread (20), pdf_start_thread (21), pdf_end_thread (22), pdf_save_pos (23), open (0), pdf_setmatrix (40), pdf_restore (42), user_defined (44), late_lua (35), pdf_colorstack (39), pdf_save (41), cancel_boundary (43), close_lua (36),

7.1.3.1 open nodes

Valid fields: attr, stream, name, area, ext

| field | type | explanation |
|--------|---------------|-------------------------------------|
| attr | <node></node> | |
| stream | number | T _E X's stream id number |
| name | string | file name |
| ext | string | file extension |
| area | string | file area |

7.1.3.2 write nodes

Valid fields: attr, stream, data

| field | type | explanation |
|--------|---------------|---|
| attr | <node></node> | |
| stream | number | T _E X's stream id number |
| data | table | a table representing the token list to be written |

7.1.3.3 close nodes

Valid fields: attr, stream

| field | type | explanation |
|--------|---------------|-------------------------------------|
| attr | <node></node> | |
| stream | number | T _E X's stream id number |

7.1.3.4 special nodes

Valid fields: attr, data

| field | type | explanation |
|-------|---------------|--------------------------|
| attr | <node></node> | |
| data | string | the \special information |

7.1.3.5 language nodes

LUATEX does not have language whatsits any more. All language information is already present inside the glyph nodes themselves. This whatsit subtype will be removed in the next release.

7.1.3.6 local_par nodes

Valid fields: attr, pen_inter, pen_broken, dir, box_left, box_left_width, box_right, box_right_width

explanation field type attr <node> pen_inter number interline penalty broken penalty pen_broken number number the direction of this par dir <node> the \localleftbox box_left box_left_width number width of the \localleftbox box_right <node> the \localrightbox width of the \localrightbox box_right_width number

7.1.3.7 dir nodes

Valid fields: attr, dir, level, dvi_ptr, dvi_h

| field | type | explanation |
|---------|---------------|---|
| attr | <node></node> | |
| dir | number | the direction |
| level | number | nesting level of this direction whatsit |
| dvi_ptr | number | a saved dvi buffer byte offset |
| dir h | number | a saved dvi position |

7.1.3.8 pdf_literal nodes

Valid fields: attr, mode, data

| field | type | explanation |
|-------|---------------|------------------------------------|
| attr | <node></node> | |
| mode | number | the 'mode' setting of this literal |
| data | string | the \pdfliteral information |

7.1.3.9 pdf_refobj nodes

Valid fields: attr, objnum

| field | type | explanation |
|--------|---------------|----------------------------------|
| attr | <node></node> | |
| objnum | number | the referenced PDF object number |

7.1.3.10 pdf_refxform nodes

Valid fields: attr, width, height, depth, objnum.

```
field type explanation
attr <node>
width number
height number
depth number
objnum number the referenced PDF object number
```

Be aware that pdf_refxform nodes have dimensions that are used by LUATEX.

7.1.3.11 pdf_refximage nodes

Valid fields: attr, width, height, depth, objnum

```
field type explanation
attr <node>
width number
height number
depth number
objnum number the referenced PDF object number
```

Be aware that pdf_refximage nodes have dimensions that are used by LUATEX.

7.1.3.12 pdf_annot nodes

Valid fields: attr, width, height, depth, objnum, data

```
field type explanation
attr <node>
width number
height number
depth number
objnum number the referenced PDF object number
data string the annotation data
```

7.1.3.13 pdf_start_link nodes

Valid fields: attr, width, height, depth, objnum, link_attr, action

```
field type explanation
attr <node>
width number
height number
```

depth number

objnum number the referenced PDF object number
link_attr table the link attribute token list
action <node> the action to perform

7.1.3.14 pdf_end_link nodes

Valid fields: attr

field type explanation

attr <node>

7.1.3.15 pdf_dest nodes

Valid fields: attr, width, height, depth, named_id, dest_id, dest_type, xyz_zoom, objnum

| field | type | explanation |
|-------------------|------------------|--------------------------------|
| attr | <node></node> | |
| width | number | |
| height | number | |
| depth | number | |
| ${\tt named_id}$ | number | is the dest_id a string value? |
| ${	t dest_id}$ | number or string | the destination id |
| dest_type | number | type of destination |
| xyz_zoom | number | |
| objnum | number | the PDF object number |

7.1.3.16 pdf_thread nodes

Valid fields: attr, width, height, depth, named_id, thread_id, thread_attr

| field | type | explanation |
|----------------------|------------------|---------------------------------|
| attr | <node></node> | |
| width | number | |
| height | number | |
| depth | number | |
| ${\tt named_id}$ | number | is the tread_id a string value? |
| tread_id | number or string | the thread id |
| ${\tt thread_attr}$ | number | extra thread information |

7.1.3.17 pdf_start_thread nodes

Valid fields: attr, width, height, depth, named_id, thread_id, thread_attr

| field | type | explanation |
|----------------------|------------------|---------------------------------|
| attr | <node></node> | |
| width | number | |
| height | number | |
| depth | number | |
| $named_id$ | number | is the tread_id a string value? |
| tread_id | number or string | the thread id |
| ${\tt thread_attr}$ | number | extra thread information |

7.1.3.18 pdf_end_thread nodes

Valid fields: attr

field type explanation
attr <node>

7.1.3.19 pdf_save_pos nodes

Valid fields: attr

field type explanation
attr <node>

7.1.3.20 late_lua nodes

Valid fields: attr, reg, data

field type explanation
attr <node>
reg number LuA state id number
data string data to execute

7.1.3.21 close_lua nodes

Valid fields: attr, reg

field type explanation
attr <node>
reg number LUA state id number

7.1.3.22 pdf_colorstack nodes

Valid fields: attr, stack, cmd, data

field type explanation
attr <node>
stack number colorstack id number

cmd number command to execute

data string data

7.1.3.23 pdf_setmatrix nodes

Valid fields: attr, data

field type explanation

attr <node>

data string data

7.1.3.24 pdf_save nodes

Valid fields: attr

field type explanation

attr <node>

7.1.3.25 pdf_restore nodes

Valid fields: attr

field type explanation

attr <node>

7.1.3.26 user_defined nodes

Valid fields: attr, user_id, type, value

field type explanation
attr <node>
user_id number id number

type number type of the value

value number

string <node> table

8 Modifications

Besides the expected changes caused by new functionality, there are a number of not-so-expected changes. These are sometimes a side-effect of a new (conflicting) feature, or, more often than not, a change necessary to clean up the internal interfaces.

8.1 Changes from T_EX 3.141592

- There is no pool file, all strings are embedded during compilation.
- plus 1 fillll does not generate an error. The extra 'l' is simply typeset.
- The \endlinechar can be either added (values 0 or more), or not (negative values). If it is added, the character is always decimal 13 a/k/a ^M a/k/a carriage return (This change may be temporary).

8.2 Changes from ε -TEX 2.2

- The ε -TEX functionality is always present and enabled (but see below about TEXXET), so the prepended asterisk or -etex switch for INITEX is not needed.
- TEXXET is not present, so the primitives

\TeXXeTstate

\beginR

\beginL

\endR

\endL

are missing

- ullet Some of the tracing information that is output by $\varepsilon\text{-TEX}$'s \tracingassigns and \tracingrestores is not there.
- Register management in LuATEX uses the ALEPH model, so the maximum value is 65535 and the implementation uses a flat array instead of the mixed flat&sparse model from ε -TEX.

8.3 Changes from PDFT_EX 1.40

- The (experimental) support for snap nodes has been removed, because it much more natural to build this functionality on top of node processing and attributes. The associated primitives that are now gone are: \pdfsnaprefpoint, \pdfsnapy, and \pdfsnapycomp.
- A number of 'utility functions' is removed:

\pdfelapsedtime \pdffilemoddate \pdfresettimer \pdfescapehex \pdffilesize \pdfshellescape

\pdfescapename \pdflastmatch \pdfstrcmp

\pdfescapestring \pdfmatch \pdfunescapehex

\pdffiledump \pdfmdfivesum

• A few other experimental primitives are also provided without the extra pdf prefix, so they can also be called like this:

\primitive \ifabsnum \ifprimitive \ifabsdim

- The definitions for new didot and new cicero are patched.
- The \pdfprimitive is bugfixed.
- The \pdftexversion is set to 200.

8.4 Changes from ALEPH RC4

The input translations from ALEPH are not implemented, the related primitives are not available

\DefaultInputMode \noDefaultInputTranslation

\noDefaultInputMode \noInputTranslation \noInputMode \InputTranslation

\InputMode \DefaultOutputTranslation \DefaultOutputMode \noDefaultOutputTranslation

\noDefaultOutputMode \noOutputTranslation \OutputTranslation \noOutputMode

\OutputMode

\DefaultInputTranslation

- A small series of bounds checking fixes to \ocp and \ocplist has been added to prevent the system from crashing due to array indexes running out of bounds.
- The \hoffset bug when \pagedir TRT is fixed, removing the need for an explicit fix to \hoffset
- A bug causing \fam to fail for family numbers above 15 is fixed.
- Some bits of Aleph assumed 0 and null were identical. This resulted for instance in a bug that sometimes caused an eternal loop when trying to \show a box.
- A fair amount of minor bugs are fixed as well, most of these related to \tracingcommands
- The number of possible fonts, ocps and ocplists is smaller than their maximum ALEPH value (around 5000 fonts and 30000 ocps / ocplists).

- The internal function scan_dir() has been renamed to scan_direction() to prevent a naming clash.
- The ^^ notation can come in five and six item repetitions also, to insert characters that do not fit in the BMP.

8.5 Changes from standard WEB2C

- There is no mltex
- There is no enctex
- The following commandline switches are silently ignored, even in non-LuA mode:

```
-8bit
-translate-file=TCXNAME
-mltex
-enc
-etex
```

- \openout whatsits are not written to the log file.
- Some of the so-called web2c extensions are hard to set up in non-KPSE mode because texmf.cnf is not read: shell-escape is off (but that is not a problem because of LUA's os.execute), and the paranoia checks on openin and openout do not happen (however, it is easy for a LUA script to do this itself by overloading io.open).

9 Implementation notes

9.1 Primitives overlap

The primitives

\pdfpagewidth \pagewidth
\pdfpageheight \pageheight
\fontcharwd \charwd
\fontcharht \charht
\fontchardp \chardp
\fontcharic \charic

are all aliases of each other.

9.2 Memory allocation

The single internal memory heap that traditional TEX used for tokens and nodes is split into two separate arrays. Each of these will grow dynamically when needed.

The texmf.cnf settings related to main memory are no longer used (these are: main_memory, mem_bot, extra_mem_top and extra_mem_bot). 'Out of main memory' errors can still occur, but the limiting factor is now the amount of RAM in your system, not a predefined limit.

Also, the memory (de)allocation routines for nodes are completely rewritten. The relevant code now lives in the C file luanode.c, and basically uses a dozen or so avail lists instead of a doubly-linked model. At this moment, speed is still a little suboptimal because separate helper structures are maintained for debugging checks.

Because of the split into two arrays and the resulting differences in the data structures, some of the Pascal WEB macros have been duplicated. For instance, there are now vlink and vinfo as well as link and info. All access to the variable memory array is now hidden behind a macro called vmem.

The implementation of the growth of two arrays (via reallocation) introduces a potential pitfall: the memory arrays should never be used as the left hand side of a statement that can modify the array in question.

The input line buffer and pool size are now also reallocated when needed, and the texmf.cnf settings buf_size and pool_size are silently ignored.

9.3 Sparse arrays

The \mathcode, \delcode, \catcode, \sfcode, \lccode and \uccode tables are now sparse arrays that are implemented in C. They are no longer part of the TEX 'equivalence table' and because

each had 1.1 million entries with a few memory words each, this makes a major difference in memory usage.

These assignments do not yet show up when using the etex tracing routines \tracingassigns and \tracingrestores (code simply not written yet)

A side-effect of the current implementation is that \global is now more expensive in terms of processing than non-global assignments.

See mathcodes.c and textcodes.c if you are interested in the details.

Also, the glyph ids within a font are now managed by means of a sparse array and glyph ids can go up to index $2^{21} - 1$.

9.4 Simple single-character csnames

Single-character commands are no longer treated aspecially in the internals, they are stored in the hash just like the multiletter csnames.

The code that displays control sequences explicitly checks if the length is one when it has to decide whether or not to add a trailing space.

9.5 Compressed format

The format is passed through zlib, allowing it to shrink to roughly half of the size it would have had in uncompressed form. This takes a bit more CPU cycles but much less disk I/O, so it should still be faster.

9.6 Binary file reading

All of the internal code is changed in such a way that if one of the read_xxx_file callbacks is not set, then the file is read by a C function using basically the same convention as the callback: a single read into a buffer big enough to hold the entire file contents. While this uses more memory than the previous code (that mostly used getc calls), it can be quite a bit faster (depending on your I/O subsystem).

10 Known bugs and limitations

The bugs below are going to be fixed eventually.

The top ones will be fixed soon, but in the later items either the actual problem is hard to find, or the code that causes the bug is going to be replaced by a new subsystem soon anyway, or it may not be worth the hassle and the limitations will eventually be documented.

Sometimes font loading via fontforge generates a message like this

```
Bad call to gww_iconv_open, neither arg is UCS4 (EUC-CN->UTF-8)
```

during font loading. This is a limitation of the internal iconv implementation.

- Font expansion does not work quite as it should. On the mailing list (sep 21), Jonathan Sauer posted a very nice test file along with an explanation.
- tex.print() and tex.sprint() do not work if \directlua is used in an OTP file (in the output of an expression rule).
- Handling of attributes in math mode is not complete. The data structures in math mode are quite different from those in text mode, so this will take some extra effort to implement correctly.
- When used inside \directlua, pdf.print() should create a literal node instead of flushing immediately.
- At the moment, only characters in plane 0 and plane 1 can be assigned catcode 13 (i.e. turned into active characters). This is a temporary measure to reduce the memory requirements of LuaTeX. In general, LuaTeX's memory footprint is a bit larger that we would like (with plain.fmt preloaded it needs about 55MB).
- Not all of ALEPH's direction commands are handled properly in PDF mode, and especially the vertical scripts support is missing almost completely (only TRT and TLT are routinely tested).
- Letter spacing (\letterspacefont) is currently non-functional due to massive changes in the virtual font handling. This functionality may actually be removed completely in the future, because it is straightforward to set up letterspacing using the LuA 'define_font' interface.
- Node pointers are not always checked for validity, so if you make a mistake in the node list processing, LuATEX may terminate itself with an assertion error or 'Emergency stop'.
- In DVI generation mode, using a \textdir switch inside the preamble of a \halign results in overprinted text in the DVI file, because the column width is not taken into account during the final placement phase (this is a bug inherited from ALEPH). Also, ALEPH apparently dislikes having more than one non-grouped \textdir command in a single lined paragraph.

11 TODO

On top of the 'normal' extensions that are planned, there are some more specific small feature requests. Whether these will all be included is not certain yet, (and new requests are welcome).

- Implement the TFX primitive \dimension, cf. \number
- Change the Lua table tex.dimen to accept and return float values instead of strings
- Do something about \withoutpt and/or a new register type \real?
- Create callback for the automatic creation of missing characters in fonts
- Implement the TFX primitive \htdp?
- Do boxes with dual baselines.
- A way to (re?)calculate the width of a \vbox, taking only the natural width of the included items into account.
- Make the number of the output box configurable.
- Complete the attributes in math and switch all the nodes to a double-linked list.
- Finish the interface from Lua to T_EX's internals, specially the hash and equivalence table (a small subpart is implementing \csname lookups for tex.box access).
- Integrate the various PDFTFX extended font codes for hz en protruding into the font table.
- Use of Type1C for embedded PostScript font subsets in traditional 8-bit encodings.
- Support font reencoding of 8-bit fonts via char index instead of via map files.
- Attempt to parse OFM level 0 fonts that are masquerading as level 1.
- Add line numbers and input context information to the lua errors
